ACTIVE IMMUNIZATION AGAINST TETANUS AND DIPHTHERIA IN INFANTS AND CHILDREN

JOHN A. BIGLER, M.D.

AND

MARIE WERNER, S.B.

CHICAGO

Prevention of certain infectious diseases by immunization has become an established part of medical practice. Active immunity produced by the introduction of an organism or its products into the body predisposes to the more rapid development of the formation of antibodies on subsequent exposure to that particular antigen. This is preferable to passive immunity because of its long duration and because usually no animal serum is used to which the recipient might be sensitive or sensitized. Passive immunity, although highly effective, has definite limitations because of its nature. It is of temporary duration; it must be given at the proper time or interval, it usually sensitizes the recipient to the serum of the animal from which it is derived or the recipient may already be an allergic person.

Active immunization of infants and children against diphtheria is now generally performed. The practical value of this procedure is so well known that further discussion is not necessary.

Although the incidence of tetanus has steadily declined, there are many reasons why active immunization against the disease would be advantageous. Cooke¹ stated that the rate of mortality from tetanus in the United States in 1930 was 1.1 per hundred thousand. Children constitute less than 30 per cent of the population, yet 50 per cent of the deaths from tetanus were among them. The infection is dreaded because of the insignificant wounds from which it may occur and because the value of tetanus antitoxin therapeutically leaves much to be desired. The mortality has been lowered considerably by the use of sedatives with the antitoxin.

Children are probably the age group most likely menaced by tetanus from the contamination of wounds with soil. The infection may develop from the most

trivial of injuries. Although passive immunity with prophylactic injections of antitoxin is highly effective, all who treat children know how difficult are the decisions to be made as to whether antitoxin should be given. The wound may be so slight or of such a nature that the parent does not seek medical aid or is not aware of the injury. Antitoxin may not be readily available, the child may be allergic, he may have received serum previously and there is always the possibility of the ever frequent serum sickness. Such thoughts may sway one in the decision to "take a chance" and withhold serum. Often, too, in delayed infections the disease will develop after passive immunity has disappeared. These are some of the reasons that speak for some method of active immunization against the disease.

Both *Corynebacterium diphtheriae* and *Clostridium tetani* produce soluble exotoxins. Ramon² in 1924 detoxified diphtheria toxin with a 0.4 per cent solution of formaldehyde and heat. Descombey³ did the same with tetanus toxin. These detoxified toxins are known as anatoxins or toxoids. Later alum precipitated toxoid was developed by flocculating the detoxified toxin with alum. Both toxins when so modified become nontoxic but retain their antigenic properties.

Jones⁴ concluded after a review of the literature and his own work that alum precipitated diphtheria toxoid is a better immunizing agent than unmodified toxoid, and this, in turn, is better than a toxin-antitoxin mixture. He found also that two injections of the alum precipitated toxoid are essential for a durable immunity and that intervals as long as three months between injections give a higher degree of immunity than when short intervals are used. This advantage of alum precipitated toxoid is due to the slow absorption of the comparatively insoluble alum precipitate. This is borne out by the work of Harrison,⁵ who found that the nodules which persist at the site of injection retain their antigenic properties for about seven weeks. Experience with tetanus toxoid also seems to bear out the enhanced value of alum precipitated toxoid over plain or unmodified toxoid.

Ramon and Zoeller⁶ demonstrated the antigenic properties of tetanus anatoxin or toxoid treated with formaldehyde. Since then both tetanus toxoid treated with formaldehyde and alum precipitated toxoid have been used to immunize human beings by Lincoln and Green-

From the Otho S. A. Sprague Memorial Institute and the Children's Memorial Hospital.

Part of the expense of this study was borne by a grant from the Elizabeth McCormick Child Research Fund of the Institute of Medicine of Chicago.

Eli Lilly & Co. supplied the tetanus and diphtheria toxoids. The tetanus toxin for titrations of serum was supplied by the National Institute of Health and Eli Lilly & Co.

Mr. F. G. Jones of Eli Lilly & Co. assisted us in establishing the mouse test technic in our laboratory and gave helpful advice in analyzing the data as well as checking a few of our titrations in his laboratory.

wald,⁷ Sneath,⁸ Sneath and Kerslake,⁹ Bergey, Brown and Etris,¹⁰ Jones and Moss,¹¹ Gold,¹² Brown and Etris,¹³ Hall,¹⁴ Hayden and Hall¹⁵ and McBryde,¹⁶ the last-mentioned author working on children.

The results of immunization against tetanus reported by the aforementioned authors showed that tetanus stimulates active immunity against tetanus. The immunizing levels of antitoxin obtained in adults vary from 0.01 to 0.1 unit and up to 2 and 3 units per cubic centimeter of serum. After the first or primary immunization a secondary injection or even subsequent (injection de rappel of the French) ones cause a rapid rise of antitoxin in the blood serum within ten days. It is suggested that if infection with tetanus spores occurs the same stimulation will take place. As yet there is no clinical evidence to corroborate this, but our present knowledge of antigenic response would lead us to believe it to be true.

There is still considerable confusion as to how much antitoxin is necessary to protect one against infection with tetanus. TenBroeck and Bauer¹⁷ have shown that an appreciable amount of tetanus antitoxin was found in the blood serum of persons in China who carried tetanus bacilli in the digestive tract. No one else has been able to corroborate this work. They expressed the belief that this accounts for the low incidence of tetanus in China, where a large percentage of the population harbors tetanus bacilli in the digestive tract. It was reported by Ramon and Lemetayer¹⁸ that since 1928 50,000 horses in the French army have been immunized with tetanus toxoid and that the morbidity and mortality have been nil. The titer of tetanus antitoxin in the blood serum of these horses averaged 0.1 to 1 unit. Ramon and Lemetayer stated that it is known that the presence of 0.001 unit is sufficient to protect the horse against infection with tetanus. Unfortunately there is no simple test simulating the Schick test to serve as a guide, even if the required protective level of antitoxin were known. For that matter not all authors have agreed as to the titer of diphtheria antitoxin in the blood serum necessary for "Schick immunity." The titers cited as necessary vary from 0.03 and 0.01 unit per cubic centimeter of blood serum to as low as 0.004 and 0.002 unit.

The incubation period of the usual infection with tetanus is from five to seven days, but it may be delayed

for from-four to five weeks. Sneath¹⁰ determined the levels of antitoxin in the blood serum of adults at various intervals after the prophylactic administration of 1,500 units of antitoxin. He found 0.1 to 0.25 unit of antitoxin per cubic centimeter of blood serum at the end of a week and 0.001 unit after four weeks. Smith²⁰ found approximately the same levels.

Cowles²¹ stated that it is probably impractical to define the minimum titer of antitoxin which will assuredly protect against tetanus. The deciding factor would seem to be the amount of toxin produced by the infection, and to predict this would be impossible. Bergey, Brown and Etris¹⁰ arbitrarily chose 0.01 unit of antitoxin per cubic centimeter of blood serum as the protective level. This can be increased rapidly by giving an additional injection of tetanus toxoid. They have shown by laboratory experiments that the circulating antitoxin, by the mouse test, does not represent the total protection. Immunized guinea pigs having 0.2 unit of antitoxin in the blood per cubic centimeter of serum, computed in terms of humoral activity, will neutralize six thousand minimum lethal doses of tetanus toxin. However, guinea pigs with that level of antitoxin will tolerate an injection of fifteen thousand minimum lethal doses of tetanus toxin without showing evidence of intoxication with tetanus. If the difference between humoral protection and total protection is non-circulating or so-called cellular immunity, then the non-circulating immunity would be at least one and one-half times greater, at least in guinea pigs. Sacquépée²² expressed the belief that from 0.1 to 0.2 unit of antitoxin per cubic centimeter of serum would probably be sufficient to give a considerable degree of immunity when one takes into consideration the sensitizing effect on the cells concerned in the production of antitoxin. Hall,¹⁴ in citing Ramon and Zoeller, stated: "To judge from the condition in the horse [tolerance of infection of a mass of tetanus spores if the serum neutralizes one single lethal dose of toxin, while a nonvaccinated horse succumbs] this antitoxin titer is still perfectly sufficient to protect these individuals against tetanus." This was said of serums neutralizing from ten to one hundred minimum lethal doses (guinea pig), that is, 0.01 to 0.1 unit of antitoxin per cubic centimeter of serum. Rawlings²³ inoculated guinea pigs with 1 cc. of refined tetanus toxoid. When these guinea pigs were infected with tetanus spores they all survived, while nonimmunized guinea pigs died within five to nine days. Jones and Jamieson²⁴ found that guinea pigs which have received one or more injections of alum precipitated tetanus toxoid are protected when infected within two months with massive doses of tetanus spores which kill normal pigs in from eighty-eight to one hundred and twelve hours. They found, however, that a massive dose of tetanus spores does not greatly accelerate the production of antitoxin in guinea pigs that have been previously immunized with alum precipitated tetanus toxoid. This is at variance with the theory of cellular immunity in that the same antigen should stimulate the production of antitoxin when that antigen has been

used previously. The immunization against tetanus of men and horses in the French army has been obligatory for several years, and to date no instance of tetanus has been reported in an immunized subject.

A unit of tetanus antitoxin is ten times more potent than a unit of diphtheria antitoxin. In other words, 1 unit of tetanus antitoxin will protect a guinea pig weighing 350 Gm. against one thousand minimum lethal doses of tetanus toxin, while 1 unit of diphtheria antitoxin will protect a guinea pig weighing 250 Gm. against only one hundred minimum lethal doses of diphtheria toxin. To calculate the amount of antitoxin in the blood serum one multiplies the titer of 1 cc. of serum by the total volume of serum, which is approximately 50 per cent of the volume of blood. The volume of blood is approximately 7.5 per cent of the subject's weight.

The use of more than one antigen at a time is not new. Multiple vaccinations against diphtheria and smallpox, diphtheria, typhoid and paratyphoid, diphtheria, typhoid and smallpox, and now diphtheria and tetanus all have been done simultaneously with a specific response of antibodies to each antigen as good as if single antigens had been used. Most children are immunized against diphtheria and smallpox near the end of the first year or during the preschool age. It would seem logical, then, to combine the diphtheria and tetanus toxoids and give them at those ages. Few children who have received immunization against tetanus, other than the group of 94 Negro children reported by McBryde,¹⁶ have had determinations done of antitoxin in the blood serum.

MATERIAL USED

The material used in this study was both the unmodified (treated with formaldehyde) and alum precipitated combined diphtheria and tetanus toxoids and alum precipitated tetanus toxoid. The diphtheria part of the mixture contained 15 to 20 Lf units per cubic centimeter. The tetanus toxoid contained thirty thousand to thirty-five thousand minimum lethal doses of tetanus toxin per cubic centimeter. The combined toxoids were standardized so that when 9 guinea pigs were each given one dose of 1 cc., the blood serum of each contained 2 units of diphtheria and tetanus antitoxin per cubic centimeter.

Dose.—Doses of 1 cc. and 0.5 cc. of the combined toxoids were used. When the alum precipitated tetanus toxoid alone was used the dose was 0.5 cc. For the primary immunization some children received two injections and some three injections at intervals varying from one to three or more months. In a few instances intervals of six months or more were allowed between the first and second injections. Stimulating or subsequent injections of either the tetanus toxoid or the combined diphtheria and tetanus toxoid have been given to some of the group six months, twelve months and longer after primary immunization. The injections were always done subcutaneously in the deltoid or triceps regions of the arm. Alternate arms were used for the injections.

PASSIVE IMMUNIZATION AGAINST TETANUS

Tetanus so rarely follows a prophylactic dose of 1,500 units of antitoxin that titers of antitoxin in the blood serum after this procedure should serve as an optimal level for protection. The titers of antitoxin in the blood were obtained on 64 children, aged 3 to 10 years, before injection and at varying intervals following the admin-

istration of the antitoxin. Before injection the blood serum from all subjects contained less than 0.003 unit of antitoxin per cubic centimeter, which is considered negligible. Titrations for lower titers were not made. As can be seen in chart 1, the level of antitoxin was highest during the first week but never was more than 0.5 unit per cubic centimeter of serum, falling to 0.2 unit during the second week, to 0.01 unit during the third week and then further declining to 0.003 unit and lower in the next two weeks. There is a wide variation in titers taken at the same interval on different children. It is evident that not all children respond the same to passive immunity, a level as low as less than 0.003 unit being present in 1 child during the first week and 0.003 unit being common during the third week. The short duration of protection from passive immunity is amply demonstrated.

ACTIVE IMMUNITY TO TETANUS

Immunization of the 240 infants and children included in this study was started in the outpatient department of the Children's Memorial Hospital. The ages of the subjects ranged from 8 months to 6 years, each age group being about equally represented. The children all received injections of the combined diphtheria and tetanus toxoids, and they all had repeated determina-

Chart 1.—Levels of antitoxin in the blood serum of children after receiving 1,500 units of tetanus antitoxin.

tions done of the antitoxin content of their blood serums. Titers of antitoxin in the blood were ascertained at varying intervals after the first, second and third injections. Titers were usually determined one to two weeks after the third injection and again later in the year.

A. After the Primary Injections or Immunization.—By these terms is meant the development of the basic immunity, such as is developed after injections of diphtheria toxoid. This basic immunity can then be stimulated by subsequent (secondary) injections at any future time. Two injections were used for the primary immunization, except in a small group which was given a course of three injections in order to determine whether there was any advantage in the latter method.

The infants and children considered in table 1 received two injections of 1 cc. of combined diphtheria and tetanus alum precipitated toxoids at intervals of three months. All blood serums on which we had titrations before immunization did not contain tetanus antitoxin in the lowest dilution for which we titrated, which was 0.003 unit per cubic centimeter. Up to three months after the first injection the serums of 12 per cent of the subjects did not contain antitoxin in the lowest dilution for which we titrated, less than 0.003 unit per cubic centimeter. The remainder had varying amounts of antitoxin up to 0.2 unit per cubic centimeter, with an average of 0.071 unit. This is in contrast to the rapid

response of antitoxin after the second inoculation. Titrations frequently were not done during the first two weeks after the second injection, as this was only a part of the primary immunization. But of the serums that were titrated during this period the lowest titer was 0.1 unit per cubic centimeter, with an average of 3.1 units. The response of antitoxin was rapid, averaging 3.52 units per cubic centimeter on the seventh day after the second injection. There was then a fairly rapid fall of antitoxin in the blood serum after one month, the average titer being 1.4 units between the first and third months, 0.26 unit up to six months and 0.22 unit up to twenty-one months. There was no regularity in the degree of response of antitoxin in different children. Although 12 per cent of the children

still had less than 0.003 unit of antitoxin per cubic centimeter of serum after the first injection, they responded as well to the second dose as those with higher levels. While some had high levels immediately after the second injection, all titers tended to decrease to a level within fairly narrow variations from the average after six months. In only 1 child was the amount of antitoxin as low as 0.003 unit three months after the second injection. Unfortunately this child could not be followed further. In 1 child with a previously high titer there was a decrease to 0.003 unit twenty months after the second injection.

A group of 15 children not included in table 1 received for the first injection 1 cc. of the combined alum precipitated toxoids and for the second injection 1 cc. of

the combined unmodified (non-alum precipitated) toxoid. The average titer of the serums of these subjects one to two weeks after the second injection was 1.73 units per cubic centimeter, from one to three months after 1.28 units and from six to twelve months after 0.14 unit. In this group 1 child had only 0.003 unit of antitoxin per cubic centimeter of serum one week after the second injection but 0.01 unit at the end of ten months. A third injection of 0.5 cc. of alum precipitated tetanus toxoid was given at this time, and at the end of seven days his serum contained 2 units of antitoxin per cubic centimeter. Another child had only 0.003 unit of antitoxin per cubic centimeter of serum two months after the second injection, which decreased to less than 0.003 unit at the end of twelve months. As this child also did not have sufficient diphtheria antitoxin after the two injections to give a positive cutaneous reaction in the rabbit with our lowest dilution of serum, which was for less than 0.002 unit, it can be assumed that he was one of those persons whose mechanism for producing antibodies cannot be stimulated, at least in diphtheria and tetanus. This was the only case in the series in which this seemed true. Unfortunately the child failed to return for further study, so that we do not know what the results of further inoculations would have been. The response to plain (unmodified) toxoid was adequate, but the average content of antitoxin in the serum was lower than when alum precipitated toxoids were used.

A third group of 14 children received as their second injection only 0.5 cc. of the combined alum precipitated

toxoid one to three months after the first injection of 1 cc. of the combined alum precipitated toxoid. One to two weeks after the second injection the lowest content of antitoxin was 0.1 unit per cubic centimeter of serum, with an average of 1.1 units. From one to three months afterward it was 1.15 units and after six to twelve months was 0.05 unit. The response of tetanus antitoxin in this group was adequate but also lower than when two injections of 1 cc. were used.

The patients considered in table 2 each received two doses of only 0.5 cc. of the combined alum precipitated toxoid as their primary immunization. After the first injection the serums of 15 per cent of the subjects did not contain antitoxin in the lowest dilution for which we titrated, which was less than 0.003 unit per cubic centimeter. The average titration of the others was 0.05 unit per cubic centimeter. Within two weeks of the second injection the average titer was 1.81 units per cubic centimeter. Only 1 child had a titer as low as 0.01 unit, the others having at least 0.1 unit. In one to three months the titers averaged 0.57 unit and in from three to twelve months 0.14 unit. Many children responded to two injections of 0.5 cc. of the combined toxoids as well as those averaging doses of 1 cc., but the average titer of antitoxin was somewhat lower. It was, however, sufficiently high to give a good immunity.

Another group of 13 children who received two 0.5 cc. doses of the unmodified toxoids developed antitoxin titers considerably lower than with the alum precipitated toxoids. There was, however, an adequate response when a third injection was given.

A definite and satisfactory response to tetanus toxoid is evident within one week after the second injection, and this response is maintained for a month. There is then a gradual drop in the content of antitoxin, but it is still probably high enough for protection up to the end of one year at least. It should be remembered, however, that the second injection of toxoid is con-

alum precipitated tetanus toxoid after an interval of from one to twelve months. There now occurred a rapid production of antitoxin to a high level, the average titer of antitoxin being 3.79 units per cubic centimeter of serum during the first two weeks. The average titer was 3.65 units on the seventh day and 4.3 units on the fourteenth day. Only 1 child had a titer as low as

sidered a part of the basic immunization, and a stimulating injection any time later produces a still higher level of antitoxin as will be shown later.

B. Effect of Stimulating or Secondary Injection of Tetanus Toxoid.—In table 3 are grouped observations on those children whose primary immunization was made up of two injections of 1 cc. of the combined toxoids and who received a stimulating or secondary injection of 1 cc. of the combined toxoids or 0.5 cc. of

0.2 unit one week after the stimulating injection, the others having titers of at least 1 unit and 1 as high as 35 units. Even though the response of antitoxin may be low after the second injection, there is good response after the stimulating inoculation, as was illustrated in a certain child. Before the first injection in this child and one and three months after the second injection no antitoxin was present in the lowest dilution for which antitoxin was titrated, i. e., less than 0.003 unit.

Ten months after the second injection his serum contained 0.01 unit of antitoxin. Within seven days after the stimulating injection 2 units of antitoxin per cubic centimeter of serum was present. As after the second injection, there again occurred a decrease in antitoxin,

as their primary immunization and who then received 0.5 cc. of tetanus toxoid one to eleven months later as a stimulating injection. There was again a rapid production of antitoxin. The average level of antitoxin was 6.78 units by the fourteenth day. This was higher

the average titer between the first and sixth month being 1.42 units and then a rapid decrease to 0.33 unit taking place by the end of the year. It is to be noted, however, that only one titer fell as low as 0.01 unit in a year, with all other titers 0.1 unit or more.

Table 4 includes observations on those children who received two doses of 0.5 cc. of the combined toxoids

than the average in the preceding group because of several high titers in such a small group. The usual decrease in levels of antitoxin occurred with an average of 1.6 units by the sixth month and 0.15 unit by the end of the year.

It is evident from the foregoing figures that a high, rapid response of antitoxin occurs in children immunized

A definite and satisfactory response to tetanus toxoid is evident within one week after the second injection, and this response is maintained for a month. There is then a gradual drop in the content of antitoxin, but it is still probably high enough for protection up to the end of one year at least. It should be remembered, however, that the second injection of toxoid is con-

alum precipitated tetanus toxoid after an interval of from one to twelve months. There now occurred a rapid production of antitoxin to a high level, the average titer of antitoxin being 3.79 units per cubic centimeter of serum during the first two weeks. The average titer was 3.65 units on the seventh day and 4.3 units on the fourteenth day. Only 1 child had a titer as low as

sidered a part of the basic immunization, and a stimulating injection any time later produces a still higher level of antitoxin as will be shown later.

B. Effect of Stimulating or Secondary Injection of Tetanus Toxoid.—In table 3 are grouped observations on those children whose primary immunization was made up of two injections of 1 cc. of the combined toxoids and who received a stimulating or secondary injection of 1 cc. of the combined toxoids or 0.5 cc. of

0.2 unit one week after the stimulating injection, the others having titers of at least 1 unit and 1 as high as 35 units. Even though the response of antitoxin may be low after the second injection, there is good response after the stimulating inoculation, as was illustrated in a certain child. Before the first injection in this child and one and three months after the second injection no antitoxin was present in the lowest dilution for which antitoxin was titrated, i. e., less than 0.003 unit.

Ten months after the second injection his serum contained 0.01 unit of antitoxin. Within seven days after the stimulating injection 2 units of antitoxin per cubic centimeter of serum was present. As after the second injection, there again occurred a decrease in antitoxin,

as their primary immunization and who then received 0.5 cc. of tetanus toxoid one to eleven months later as a stimulating injection. There was again a rapid production of antitoxin. The average level of antitoxin was 6.78 units by the fourteenth day. This was higher

the average titer between the first and sixth month being 1.42 units and then a rapid decrease to 0.33 unit taking place by the end of the year. It is to be noted, however, that only one titer fell as low as 0.01 unit in a year, with all other titers 0.1 unit or more.

Table 4 includes observations on those children who received two doses of 0.5 cc. of the combined toxoids

than the average in the preceding group because of several high titers in such a small group. The usual decrease in levels of antitoxin occurred with an average of 1.6 units by the sixth month and 0.15 unit by the end of the year.

It is evident from the foregoing figures that a high, rapid response of antitoxin occurs in children immunized

against tetanus after a stimulating injection of tetanus toxoid or the combined toxoid. The immediate response of antitoxin was as good in those children immunized with doses of 0.5 cc. of the combined toxoids as it was when doses of 1 cc. were used. Although these children received their stimulating injections only one to twelve months after being immunized, our results with intervals up to two years have been the same in a few children so inoculated. In fact, the longer intervals, in table 4, seem to account for the average level of antitoxin being higher than it is in table 3.

INFLUENCE OF THE INTERVAL BETWEEN INJECTIONS

Jones⁴ has pointed out that by increasing the interval between injections for immunization against diphtheria a better immunity will result. This seems to hold true for immunization against tetanus. In chart 2 are given

NUMBER OF INJECTIONS FOR PRIMARY IMMUNIZATION

We were interested in knowing whether a series of three injections had any advantage over a series of two injections to establish the primary immunization. In chart 3 are given the average titers of antitoxin in the blood serum of two groups, one given two and the other three injections. When three injections were used the initial response of antitoxin was no higher than when two injections were used, but the levels remained somewhat higher. The average titer of antitoxin was 3.5 units within one month in both groups. In the group given three injections at the end of six months the average was 0.9 unit and by the twentieth month it was 0.35 unit, as compared to 0.25 unit and 0.23 unit respectively in the group given two injections. It is apparent that three injections are superior to two injections for primary immunization when the height of the response

the levels of antitoxin following an interval of one to two months and those with an interval of six months or more between the first and second injections of the primary immunization. With the longer interval the immediate response of antitoxin is much higher, averaging nearly 20 units as compared to about 5 units for the shorter interval. There is then a rapid decrease in levels of antitoxin, so that by the end of a year the levels in the long and the short intervals are approximately the same.

This same difference in response of antitoxin has been found to hold true when a stimulating or secondary injection is given. The average titer of antitoxin two weeks after a stimulating injection was only 2.6 units per cubic centimeter of serum when intervals up to three months were used, but when the interval was six months to one year the average titer was 6.88 units. By the end of a year the antitoxin content of the serum approached approximately the same level, irrespective of the interval between injections. It would seem that an interval of three or more months between the injections of the primary immunization would be desirable, although an adequate immunity does follow intervals of one to two months.

of antitoxin is considered. There were no low titers in the group given three injections such as are at times encountered with two injections, as may be seen in table 1.

The same type of curve is present when injections of 0.5 cc. of the combined toxoids are used (chart 4).

The only advantage of three injections is the establishment of a higher level of antitoxin for about six months. If three injections are to be used, doses of 0.5 cc. will give as good a response as two doses of 1 cc. With this method we have experienced no titers lower than 0.5 unit within three months of the third injection.

The stimulating injection given three months to one year after the primary immunization (both in the group given two and in that given three injections) produces a rapid and high response of antitoxin which decreases in six months to, and continues at about, the same level as that in the group given three injections (charts 3 and 4).

DURATION OF IMMUNITY

It has not been established how long the immunity developed by immunization against tetanus lasts. As yet there have been no cases of tetanus reported as occur-

ring in man or in horses immunized several years ago.¹⁸ The number so immunized has been large when one considers that this procedure has been obligatory in the French army as just one group. Whether or not the basic immunity which develops from the primary immunization is sufficient for protection from the infec-

Chart 2.—Comparison of six month interval and two month interval between first and second injections of combined alum precipitated diphtheria and tetanus toxoids as to titers of tetanus antitoxin. A. U., antitoxin units.

tion, as it generally is in diphtheria, is not known. For that reason it is advisable at present to use stimulating doses of toxoid when an injury likely to be infected with tetanus spores occurs. Theoretically this should not be necessary, but only time will give the final answer. In chart 5 are given curves for the average titers of antitoxin as we have found them in our group of children over a period of two years. By the end of two years after the primary immunization several titers were as low as 0.01 unit (one decreasing to 0.003 unit), while after a third injection no titers decreased below 0.1 unit except two at the 0.01 unit level. There was little if any change during the second year. No child has failed to have a rapid response of antitoxin at any time to a stimulating or secondary injection of toxoid.

Chart 3.—Titers of tetanus antitoxin after primary immunization with doses of 1 cc. of combined toxoids and stimulating injection: a, two injections one to three months apart; b, three injections one to three months apart; c, stimulating injection more than three months after primary immunization.

IMMUNITY AGAINST DIPHTHERIA

Schick tests were not done on any of the children to eliminate the stimulation to the production of antitoxin which might occur from the small doses of toxin. The

titration for antitoxin was done on the child's blood serum by the rabbit skin test method. The response to the combined toxoids varied according to whether some antitoxin was previously present either from natural immunity or from previous immunization to diphtheria. The titers of the blood for one group of children immunized are given in table 1. Three months after the first injection of the combined toxoids 19 per cent of the children still had 0.002 unit or less of antitoxin per cubic centimeter of serum. This would seem to corroborate the opinion that one injection of toxoid is not sufficient for satisfactory immunity. When appreciable amounts of antitoxin had been previously present, titers from 1 to 5 units were found. In the others the usual titers were between 0.01 and 0.1 unit per cubic centimeter of serum.

After the second injection there was a rapid rise in the titers within two weeks. In only 2 children of all those to whom we have given the injections was there some failure in the production of antitoxin. In 1, 0.002 unit of antitoxin was present two weeks after the second injection. Unfortunately this child failed to return for further study. In another child not included in the tables no antitoxin was present in the lowest dilution for which his serum was titrated (less than 0.002 unit) before immunization, one and three months after the

Chart 4.—Titers of tetanus antitoxin after primary immunization with doses of 0.5 cc. of combined toxoids and stimulating injection: a, primary immunization (average of two and three injections); b, stimulating injection.

first injection and twelve months after the second injection. He has as yet not received a third injection. This child undoubtedly was one of those persons resistant to the production of antitoxin, because there was also a complete failure of response of tetanus antitoxin over the same period. After the rapid increase of antitoxin immediately following the second injection there occurs a fall in the level of antitoxin to 0.01 to 0.1 unit by the end of two years in many children. One level decreased to 0.002 unit in twelve months. This decrease in diphtheria antitoxin is more rapid than that of tetanus antitoxin, and the levels are not nearly so high at any time.

When injection of the combined toxoids is given in doses of 0.5 cc., a satisfactory response of antitoxin occurs (table 2). In fact, the titers of antitoxin are comparable to those resulting from doses of 1 cc. of the combined toxoids.

In those children receiving a third dose of the combined toxoids one to several months after the second injection there was again a rapid rise in the titer of antitoxin (table 3), the levels of antitoxin varying from 0.1 to 5 units. Again followed a decrease in the titers,

so that by the end of a year many of these were as low as 0.01 to 0.1 unit. There is usually no response of diphtheria antitoxin when only tetanus toxoid is used for the third injection. We cannot account for the occasional variation in titers of diphtheria antitoxin which occurs after the injections of tetanus toxoid.

Chart 5.—Duration of immunity to tetanus following primary immunization and stimulating injection: *a*, primary immunization (average of two and three injections); *b*, stimulating injection.

If one increases the interval between the first and second injections from three to six months or more there is a greater immediate response of antitoxin, as occurs with immunization against tetanus. There is, however, a more rapid fall in diphtheria antitoxin, so that after the second month the average level of antitoxin is the same irrespective of the interval (chart 6).

The duration of immunity, as evidenced by the presence of antitoxin, follows about the same curve as for tetanus antitoxin. There was a fairly rapid decrease in antitoxin up to the sixth month, after which the usual titers remained between the levels of 0.01 to 0.1 unit for the two years for which we have checked them (chart 7).

Immunity Response According to Age.—There was little difference in the immunity response according to age. The infants under 18 months of age had a slightly higher average response of antitoxin than the other chil-

Chart 6.—Comparison of six month interval and two month interval between first and second injections of combined alum precipitated diphtheria and tetanus toxoids as to titers of diphtheria antitoxin.

dren up to 5 years of age. This was true after the initial immunization as well as after a stimulating or secondary injection. The titers we obtained were approximately the same as those found by McBryde in his group of children, but they definitely ran much higher than those found in adults.

Immunity Response of Allergic and Nonallergic Children.—When the immunity response of allergic children was compared to that of nonallergic children it was found that the levels of antitoxin averaged moderately higher in the latter group.

Immunization with Combined Diphtheria and Tetanus Toxoids.—The combined toxoids always produced a much higher initial titer of tetanus antitoxin than did tetanus toxoid alone, which was used on a small group of children. Six months or more after inoculation the titers produced by the two products averaged about the same. Both always produced protective levels when compared to 1,500 units of tetanus antitoxin. Titers of diphtheria antitoxin with combined immunization were as high as if not higher than those reported from immunization against diphtheria alone. Furthermore, there were fewer levels of antitoxin below those required for Schick immunity with the combined toxoids. Tetanus toxoid alone did not influence the level of diphtheria antitoxin in the serum.

REACTIONS

The reactions following the administration of combined diphtheria and tetanus toxoids are no different from those following the use of alum precipitated diphtheria toxoid. There is stinging and burning at the site of injection which lasts for several minutes, as it does

Chart 7.—Titers of diphtheria antitoxin following first and second injections of combined alum precipitated diphtheria and tetanus toxoids: *a*, one injection; *b*, two injections.

also with plain toxoid. There is usually a hard nodule present which may persist for several weeks as it decreases in size. Occasionally the inoculated area may become reddened for about twenty-four hours, and some tenderness may also be present. In several hundred inoculations that we have done we have never encountered an abscess or an area which gave the appearance of the formation of an abscess. In a few instances there was a mild general reaction, with a low fever and mild malaise for about twelve hours. The reactions were much fewer and less violent than those we have encountered in immunization against pertussis. They were about the same as those encountered when unmodified diphtheria toxoid was used.

In 1 of the 300 children to whom we had given either tetanus toxoid or the combined diphtheria and tetanus toxoids a rash developed after the first inoculation which from the mother's description we felt was moderately severe urticaria. It developed within a few hours of the injection and lasted for several hours. There was no recurrence after the second injection. We saw another child in whom urticaria developed, a physician's child who had an allergy to pollen. After the first injection given by the father a few urticarial lesions appeared. Three months later, immediately after the

second injection, moderately severe urticaria again developed. This responded promptly to an injection of epinephrine. We have encountered no other symptoms of allergy, although about half of the children had some form of allergy. Many of the infants had severe eczema when the injections were given. Many of the older children had hay fever and asthma at the time they were inoculated. Some were receiving injections of antigens for their allergies during the same period in which they were being immunized. In none of these children was there any aggravation of their symptoms of allergy.

We gave injections also to some children with infections of the upper part of the respiratory tract with and without fever. In 2 instances in which children had temperatures of 102 to 103 F. the temperatures rose to 105 F. This may or may not have been due to the inoculation. Both recovered from their infections in a normal manner. We do feel from this experience that it is not advisable, without definite indication, to give injections of toxoid when fever is present.

INTRADERMAL IMMUNIZATION

We are at present using intradermal injections, at intervals of from one to three months, of the combined toxoids or of tetanus toxoid in a group of 32 children in doses of 0.05 to 0.1 cc. This group has as yet not been studied long enough for us to draw final conclusions as to the efficacy of this method of immunization. From two weeks to nine months after the second injection the blood serum of 9 of the children did not contain any tetanus antitoxin in the lowest dilution for which it was titrated, which was less than 0.003 unit per cubic centimeter, 6 had a titer of only 0.003 unit and the rest had titers of 0.01 to 0.1 unit with only 1 as high as 0.5 unit. Two children were given a third injection, and within three weeks the titer of antitoxin had increased from 0.01 to 0.1 unit in 1 and from 0.1 to 0.5 unit in the other. Two intradermal injections of the toxoids produce a low level of antitoxin. A subsequent report on this procedure will be made.

COMMENT

There is a great variation in the responses of individual children to tetanus and diphtheria toxoids as measured by the level of antitoxin in the blood serum. For tetanus antitoxin the levels vary from less than 0.003 to 35 units per cubic centimeter of serum, and for diphtheria antitoxin they vary from less than 0.002 to 15 units per cubic centimeter. There is no relationship in the amount of tetanus antitoxin as compared to the amount of diphtheria antitoxin which will develop in the same person from injections of toxoid.

A few persons seemed to respond poorly to injections of toxoid when the response was measured by the production of antitoxin. In this group of infants and children 1 child failed in the production of both tetanus and diphtheria antitoxin. Before injection of the toxoids the titer of diphtheria antitoxin was less than 0.002 unit, being the same after the first injection and also two weeks and twelve months after the third injection. The titer of tetanus antitoxin at these same periods was less than 0.003 unit. One child failed to have more than 0.003 unit of tetanus antitoxin three months after the second injection, although the response of diphtheria antitoxin was adequate. Another child, while having an adequate response of tetanus antitoxin developed only 0.002 unit of diphtheria antitoxin within

two weeks after the second injection. We cannot classify these last patients, as failing to respond, because it was not possible to get their reaction to a third injection.

It is apparent from this study that intervals of three to six months between injections result in a better immunity response than do shorter intervals.

Two injections of 1 cc. of combined diphtheria and tetanus toxoids produce an adequate basic immunity as measured by the response of antitoxin. There was one possible failure for both diphtheria and tetanus toxoids and one other each for diphtheria and for tetanus. Two injections of 0.5 cc. of the combined toxoids also produced an adequate immunity in a small series with no apparent failures. In this group some were given a series of three injections with a response similar to that of the group receiving two injections of 1 cc. This basic immunity as measured by the response of antitoxin seemed to be adequate for several months, especially when there were intervals of three or more months between injections.

A stimulating or secondary injection of tetanus toxoid or the combined toxoids always produced a high titer of tetanus antitoxin which was much superior to that following the giving of 1,500 units of antitoxin both as to amount and as to the length of time high titers were present in the blood stream.

From this study it would seem that the combined immunization against tetanus and diphtheria of infants and children is both practical and possible. The apparent failures of immunization against tetanus gaged by the production of antitoxin were no more frequent than were those experienced in immunization against diphtheria. Because of the uncertainty which is still present as to the response of children immunized against tetanus to an infection with tetanus spores, it is advisable to give a stimulating dose of tetanus toxoid when a suggestive injury occurs.

For the child who has already been immunized against diphtheria and who is to be immunized against tetanus it would seem advisable but not necessary to give the first injection of the combined toxoids and the second injection of tetanus toxoid alone, or, if one so desires, the combined toxoids can be used for both injections.

CONCLUSIONS

1. Combined immunization against tetanus and diphtheria of infants and young children is possible, as evidenced by the antitoxin content of the blood serum.

2. A stimulating dose of tetanus toxoid given to an immunized child causes a rapid and high response of antitoxin.

3. In the light of our present knowledge there are no more failures in immunization against tetanus than there are in immunization against diphtheria.

4. The duration of immunity to tetanus as measured by the level of antitoxin in the blood serum was as good as the immunity to diphtheria during the two years of observation.

5. Two injections of 1 cc. of the combined toxoids or three injections of 0.5 cc. produce an adequate basic immunity. The use of three injections of 1 cc. for basic immunity, although producing higher levels of antitoxin, does not seem to be necessary.

6. Intervals of three months or more between injections enhance the response of antitoxin.

7. Combined immunization against tetanus and diphtheria would seem as practical as immunization against diphtheria alone.

8. Reactions to injections of combined tetanus and diphtheria toxoid are no more frequent or severe than they are with diphtheria toxoid.

9. Prophylactic injections of tetanus antitoxin produce a protective level of antitoxin for only a few weeks. This level is not as high as that after immunization with tetanus toxoid nor does it last nearly as long.

10. It is apparently safe to administer tetanus and diphtheria toxoids to allergic children. Sensitization to the toxoids is rare. This is in contrast to the antitoxins used for passive immunity.

11. In the light of our present knowledge it would seem safer to give an immunized person a stimulating dose of tetanus toxoid after an injury involving probable infection with tetanus spores.

CHEMOTHERAPY VERSUS COMBINED CHEMOTHERAPY AND SERUM

IN THE TREATMENT OF PNEUMONIA
A STUDY OF 607 ALTERNATED CASES

NEW YORK

The universal acceptance of the value of sulfonamide therapy in pneumonia has left the role of serum as the major current problem in the treatment of this disease. Will the use of serum combined with drug reduce still further the fatality rate? Will it cause a more rapid subsidence of the acute infectious process? These problems have been studied at Bellevue Hospital by using the alternate case method. Since February 1939, all pneumonia patients entering the wards of the First, Second and Fourth medical divisions have been alternated within the pneumococcus types between sulfonamide therapy alone and combined drug and serum therapy. In the present study we are reporting the results up to Jan. 1, 1941 in a series comprising 607 patients thus alternated.

METHOD

As soon as the clinical diagnosis of pneumonia was made, samples of blood and sputum were collected for bacteriologic study. The patient was then immediately placed on sulfonamide therapy without waiting for the results of typing. When the pneumococcus type was obtained, alternate patients in each type were placed in either the drug alone or drug plus serum group. If the patient fell in the drug plus serum group he was given, in addition to the drug, concentrated antipneumococcus rabbit serum. This was administered as soon as the specific type was obtained except when striking

clinical improvement already had occurred and serum no longer would be of value. These patients, however, were left in the "drug-plus-serum" group because to remove them would create a statistical error in favor of the drug-alone series. The first therapeutic dosage of serum was usually 100,000 units in uncomplicated cases and 200,000 units or more for known bacteremic or seriously ill patients. This dosage was repeated when necessary. Six patients who would have been due for serum survived less than twenty-four hours and died before typing was completed. These patients, therefore, received no serum but were necessarily counted in the serum group, it being one of the inherent disadvantages of serum therapy that there usually is some delay before serum can be started even under ideal circumstances. With the exception of these six twenty-four hour deaths, all other patients in the serum group who died received serum.

Several different sulfonamide drugs were used during the course of this study: sulfapyridine, dextrose-sulfapyridine, sodium sulfapyridine, sulfathiazole, sulfamethylthiazole and sulfadiazine. When a new drug was introduced, one or more whole wards were shifted from one drug to the other, and all patients entering these wards were treated with the new drug without interfering with the alternation of cases between the drug-alone and the combined therapy groups. There was an occasional failure of response, and occasionally a maintenance dose higher than 1 Gm. every four hours was used. A few patients received sodium sulfapyridine intravenously either to obtain a more rapid absorption or to procure a higher blood concentration of the drug.

Other forms of treatment including oxygen therapy, procedures for maintaining an adequate fluid intake, sedation and various symptomatic measures were used as indicated in both groups of cases.

This study included cases of both lobar pneumonia and bronchopneumonia. No patients were excluded except those with atypical congestive bronchopneumonia terminating some otherwise fatal disease such as carcinoma or heart disease. All other cases of pneumonia were included: systemic disease, no matter how serious, did not disqualify patients. A complete bacteriologic study was carried out in all cases; throat swab cultures were made when sputum was not obtainable; typing was repeated in all of the higher types and whenever the results were not conclusive; typing from the peritoneal exudate and from the brain of the mouse was used to supplement and confirm the findings in every case; admission blood cultures were always procured and repeated when indicated; chest fluid, or any other specimen from a localized process obtainable either ante mortem or post mortem was sent to the laboratory for study. In addition almost every patient had at least one roentgen examination, blood counts, urinalyses and blood chemistry determinations, particularly the sulfonamide drug concentration.

COMPARATIVE EFFECT ON THE MORTALITY RATE

The effect of the two modes of therapy on the fatality rate is shown in table 1. Of 306 patients treated with chemotherapy alone, 34 (11.1 per cent) died. Of 301 patients treated with chemotherapy plus serum, 44 (14.6 per cent) died. However, if patients dying within twenty-four hours of the start of treatment are excluded, the mortality rates become nearly equal, 9.3 per cent for the drug group and 9.8 per cent for the drug-plus-serum group. It is noteworthy that even in types I, II,

This investigation has been conducted under a grant of the Josiah Macy, Jr. Foundation. The serum and drugs used were supplied by the Lederle Laboratories, Inc., and in part by the Winthrop Chemical Company.

From the First (Columbia), Second (Cornell) and Fourth Medical Divisions, Bellevue Hospital, and the Departments of Medicine of the Columbia University College of Physicians and Surgeons and Cornell University Medical College, and a Committee for Pneumonia Investigation consisting of Drs. Russell L. Cecil, I. Ogden Woodruff, Asa L. Lincoln and Charles H. Nammack (the latter three, directors of the First, Second and Fourth Medical Divisions respectively) and the authors.

V and VII, in which the value of serum is best established, the fatality rates were not significantly lower in any of the drug-and-serum groups.

COMPARATIVE EFFECT IN BACTEREMIC PATIENTS

In the drug-only group there were 61 bacteremic patients, of whom 20 (32.8 per cent) died, four within twenty-four hours. In the drug-and-serum group, 64 were bacteremic and 29 (45.3 per cent) died, 14 within twenty-four hours. Excluding the twenty-four hour deaths, the mortality rate in the drug group was 28.1 per cent and in the drug-and-serum group 30.0 per cent.

The incidence of bacteremia in this study is 20.6 per cent. This is lower than the incidence in previously reported Bellevue series, because under effective sulfonamide therapy patients rarely develop bacteremia after treatment is commenced. In this series we encountered

no patient whose blood culture was sterile on admission and became positive during treatment.

There were 4 bacteremic patients in this series whose plates showed innumerable colonies of pneumococci and who recovered. In the Bellevue experience in the pre-chemotherapeutic era, all such patients died. As it happened, these 4 patients were all in the drug-alone group, and each was treated with a different drug, viz. sulfapyridine, sulfathiazole, sulfamethylthiazole and sulfadiazine. It is remarkable that any patients with such severe infections should recover, and noteworthy that they were all in the drug-alone group.

RESULTS IN EARLY AND IN LATE CASES

In order to evaluate further the effect of the two modes of therapy, all cases were divided according to the duration of illness before treatment was begun. They were grouped into three classes: early (treatment started during the first three days), late (treatment begun on the fourth day or later) and uncertain (duration of illness not ascertainable). The last group for the most part comprised patients entering when moribund, or nearly so, and were consequently usually late cases. The results of treatment are given in table 3.

Of the 158 early cases in which drug-alone treatment was employed there were 7 deaths (4.4 per cent); of the 146 early cases (one twenty-four hour death excluded) in the drug-and-serum group there were 10 deaths (6.8 per cent).

In the "late" group (omitting twenty-four hour deaths) there were 117 cases in the drug group with 14 deaths (12.0 per cent) and a total of 110 cases in the drug-and-serum group with 11 deaths (10.0 per cent). In the "uncertain" group (omitting twenty-four hour deaths) there were 26 in the drug group with 7 deaths (26.9 per cent) and 28 cases in the drug-and-serum group with 7 deaths (25.0 per cent). Combining the "late" and "uncertain" groups we have a total of 143 cases with 21 deaths (14.7 per cent) in the drug group and 138 cases with 18 deaths (13.0 per cent) in the drug-and-serum group. Thus it can be seen that the fatality rate in the patients treated early, whether by

TABLE 3.—Results in Early Cases (First Three Days) Compared with Those in Late Cases and in Cases of Uncertain Duration

drug alone or by drug and serum, was about one-half the fatality of the late and uncertain cases combined; this emphasizes anew the well known fact that early treatment is essential if the best results are to be obtained. The additional routine use of serum did not materially affect the outcome in the early, in the late or in the uncertain group.

COMPARATIVE EFFECTS ON RAPIDITY OF RECOVERY

It is not easy to judge the effect of the two modes of therapy on the rapidity of recovery. We have elected to estimate this by making composite temperature curves (charts 1 and 2) of the type I and of the type II cases in the two therapeutic groups in which survival

Chart 1.—Comparative temperature response in type I cases.

occurred. In these two types the effect of serum therapy has been most completely studied, and if differences in rapidity of response are to be found they should be apparent here. As can be seen, there is no significant difference in the two temperature curves for each type, nor could any consistent difference in the two therapeutic groups be noted clinically. The serum was given at varying intervals after the start of drug treatment, depending on the speed of typing but usually within the first twenty-four hours.

AGE OF PATIENTS

The patients comprising this study were older, on the whole, than those in most other reported studies, the average age for the entire group being 49.3 years. The distribution by age is shown in table 4. The average age for the drug group was 49.2 years, for the drug-plus-serum group 49.3 years. There were no deaths in either group in patients under 30 years of age. Between 30 and 50 the fatality rate was 3.4 per cent in the drug group and 4.9 per cent in the drug-and-serum group. For patients 50 or more years of age, the fatality rate was 16.1 per cent in the drug group and 16.8 per cent in the drug-and-serum group.

DRUG LEVELS AND AMOUNT OF SERUM USED

Blood level estimations were done frequently on most of the patients during the active stage of the disease.

Chart 2.—Comparative temperature response in type II cases.

Our data are not complete enough, however, to allow us to draw any definite conclusions. In experimental infections in animals treated with sulfonamides, Marshall¹ has shown that the percentage of animals sur-

living depends on drug dosage and drug level, high doses and levels increasing the survival rate. It is probable that this applies to human cases of pneumonia also, but we are unable to state what constitutes the optimum blood level of drug. In practice the estimation of blood levels has been of value chiefly for those patients who have not responded satisfactorily or who have had impaired renal function. If failure of a patient to respond appears to be due to a low blood level, parenteral or increased oral administration of the drug can be used. An initial dose of 2 Gm. was used in all our cases. That a larger initial dose would have saved a substantially greater number of patients seems to us unlikely.

The amount of serum used varied from 80,000 to over 600,000 units; for patients who died but survived long enough to receive serum, the average dose was 260,000 units.

RESULTS ACCORDING TO DRUG USED

There seemed to be no significant difference in the fatality rates for the different sulfonamide compounds used, although several of the compounds were not tried extensively enough to offer conclusive evidence on this point (table 5). All the compounds were potent remedies for pneumonia, although the dextrose-sulfapyridine solution used (10 per cent in 50 per cent dextrose

TABLE 4.—Distribution of Cases and Results by Age

given orally) was a little less efficient than the other drugs in the cases of bacteremia. This may have been due to the slower absorption of this drug. The sodium sulfapyridine cases comprise those in which tablets of this drug were administered orally. A few patients were given supplementary intravenous injections of sodium sulfapyridine but were not treated exclusively in this way.

COMPLICATIONS OF PNEUMONIA

The complications are listed in table 6. All of the 10 patients with pneumococcal endocarditis diagnosed clinically died regardless of the type of therapy used, and none of the patients with pneumococcal meningitis following pneumonia recovered. There were 11 patients with empyema in the drug-alone group; of these 2 died (1 within twenty-four hours and 1 with pneumococcal endocarditis) and 4 came to thoracotomy. Of the 13 empyema patients in the drug-and-serum group 4 died (1 within twenty-four hours, 1 with meningitis and 1 with probable pneumococcal endocarditis), and 7 required thoracotomy. The remaining empyema patients in each group had thin fluid and recovered on repeated thoracenteses and continued oral administration of the drug. Fluid was demonstrated or suspected on admission in 7 of the 11 cases in the drug-alone group and in 5 of the 13 cases in the drug-and-serum group. There were 5 cases of sterile serous effusion in the drug-alone group and 16 in the drug-and-serum group; of these cases, in 2 in the drug-alone group and in 7 in

1. Marshall, E. K., Jr.: Experimental Basis of Chemotherapy in the Treatment of Bacterial Infections, *Bull. New York Acad. Med.* 16: 723-731 (Dec.) 1940.

the drug-and-serum group there was demonstrable or suspected fluid on admission. There were 5 cases of non-putrid lung abscess, and it is our impression that perhaps more abscesses as sequelae of pneumonia will be

seen in the future than in the past, because some of the most acutely ill patients with heavy bacteremia, who in the past did not survive the acute stage of the disease, now live long enough to allow tissue breakdown to occur. This subject of pleural and parenchymal complications of pneumonia under modern therapy will be reported in detail in a subsequent communication.

Four of the women in this series were pregnant; 2 were in the drug-alone and 2 in the drug-and-serum group. All recovered. Two were bacteremic; 1 had 12 colonies per cubic centimeter of blood and recovered on drug and serum; the other had innumerable colonies in the blood and recovered on sulfadiazine alone. The latter patient went into labor after being in the hospital twenty-four hours and also had a thin empyema which was cured without surgery. All these patients were in the seventh or eighth month of pregnancy and only 1 did not deliver during the acute stage of the disease.

DRUG AND SERUM REACTIONS

The toxic reactions ascribed to the sulfonamide drugs are listed in table 7. There were not enough cases in which treatment by every one of the individual drugs was given to make a comparative table of incidence which would be of statistical significance. However, it can be said that there was frequent and severe nausea and vomiting with sulfapyridine, dextrose sulfapyridine and sodium sulfapyridine, considerably less nausea and vomiting with sulfathiazole and sulfamethylthiazole, and practically none with sulfadiazine. The serious toxic reactions were infrequent with any of the drugs and were rather well distributed.

* In three of these cases the diagnosis was confirmed at autopsy.

Only one fatality due to chemotherapy occurred, a case of toxic hepatitis and aplastic anemia due to sulfapyridine. In 1 of the sulfamethylthiazole cases already reported,² peripheral neuritis developed following the administration of 72 Gm. of the drug.

2. Solomon, Saul, and Kalkstein, Mennasch: Sulfamethylthiazole in Treatment of Severe Type II Bacteremic Pneumonia, New York State J. Med. 41: 270-272 (Feb. 1) 1941.

Serum reactions consisted in a small number of chill reactions and an occasional mild serum sickness. Once a questionable anaphylactic reaction possibly contributed to a patient's demise an hour after the serum had been administered.

THE FATAL CASES

Of the 78 patients who failed to survive, 22 were admitted moribund or nearly so and died within twenty-four hours of admission. Of the remaining 56, 26 had some other serious systemic disease in addition to pneumonia. A list of the chief additional diseases occurring in the fatal cases is presented in table 8. The average age of the patients who died was 59.4 years for those receiving drug alone and 61.8 years in the drug-and-serum group. Although alcoholism occurs frequently in our Bellevue patients, for lack of reliable data we have not listed it as an associated systemic disease unless there was accompanying hepatomegaly and jaundice. It will be noted that many of the associated diseases were or of themselves would have become fatal, but because

serum than by either agent alone. MacLeod,⁶ in experimental type III infections of mice, Kepl and Gunn,⁷ in early type I infections in rats, and Powell and Jamieson,⁸ using a variety of types in rats, have obtained better results with sulfapyridine and serum together than with either agent alone. However, Wright and Gunn⁹ failed to get better results in type III infections in rats with combined therapy than with sulfapyridine alone, or in the longer established type I infections.⁷

Haviland,¹⁰ in studying type I pneumonia in human beings, found that administration of serum as well as drug maintained antibodies in the blood during the whole course of the disease. He suggests that, instead of waiting for the appearance of antibodies (which with drug treatment alone may not occur for several days after the temperature has fallen to normal), 100,000 units of serum be given routinely four hours after the start of chemotherapy. This is a theoretical consideration which is yet to be shown to have practical application, particularly since it has been demonstrated¹¹ that some patients may recover without demonstrable antibodies in the blood and that others may die despite the presence of a high titer of antibodies.

Bullowa, Bukantz and de Gara¹² have presented suggestive evidence that the presence of free capsular polysaccharide in the blood stream implies a more serious prognosis than does bacteremia alone and that sulfapyridine, alone or even with specific serum, may not cure such patients. They state that "it remains for further observations to determine whether or not a greater reduction in mortality of pneumococcal pneumonias, or other pneumococcal infections, may be accomplished by the inclusion of this laboratory criterion as a guide to therapy."

With respect to the application of experimental results to the treatment of patients, the literature is replete with opinions as to the role that serum should play in the treatment of pneumonia, but, as Finland¹³ points out, there is little basis for estimating the relative efficiency of combined therapy compared with chemotherapy alone, in spite of the large number of cases included in a host of clinical reports.

To the best of our knowledge, only two studies have appeared on the use of serum in other ways than merely in seriously ill patients, Bullowa and his associates⁴ have reported a series of 324 cases rotated in treatment three ways; the mortality rate in the group receiving serum alone was 17.3 per cent, in the group receiving sulfapyridine alone, 8.1 per cent, and in the group treated with both agents, 11.2 per cent. Dowling,

Abernethy and Hartman¹⁴ have recently reported a series of 162 cases alternated between drug therapy and combined therapy; the mortality rate was 12.5 per cent in the drug alone group and 9.8 per cent in the drug plus serum group. The authors felt that the patients who received serum as well as sulfapyridine responded more promptly, and that serum seemed to be a valuable adjunct to sulfapyridine in patients over 40 years of age.

Our clinical results confirm the previously reported failures in smaller series to affect the mortality rate to any significant extent by using serum routinely in addition to chemotherapy, regardless of the stage of the disease in which treatment is started. We have not noted more prompt responses in the patients receiving combined therapy.

What, then, is the present role of serum in the treatment of pneumonia? There will probably be no disagreement with the statement that serum should be used for patients who cannot tolerate the sulfonamide drugs or for those who fail to respond satisfactorily within twenty-four to forty-eight hours to drug therapy. However, our study certainly provides no argument for the routine use of serum in the treatment of all cases of pneumonia. Whether the patient was treated early or late in the disease, whether bacteremia was present or not, whether the patient was young or old, and regardless of the presence or absence of systemic disease, our results were the same in the drug-alone as in the drug-plus-serum group. The group of patients who cannot tolerate sulfonamide therapy probably should include those who have had a previous serious reaction to such therapy, e. g. granulocytopenia, hepatitis or hemolytic anemia. When sulfonamide therapy has to be discontinued before its full benefit has been obtained, administration of serum may be helpful in furthering the response or in preventing relapse.

In our private practice we have used serum several times with gratifying results for patients who failed to respond to chemotherapy. Whether these patients would not eventually have recovered without the additional use of serum we cannot say. Our Bellevue study would lead us to believe that they would have done so. In the Bellevue group there were a number of delayed responses to chemotherapy. We were constantly on the lookout for patients in the drug-only group to whom we might feel that an injustice had been done in not giving serum, but when the completed data were analyzed we found no such cases.

SUMMARY AND CONCLUSIONS

1. A series of 607 cases of pneumococcal pneumonia was alternated in treatment, by type, between chemotherapy and combined chemotherapy and serum therapy.

2. The fatality rate in the drug-alone group was 9.3 per cent, in the drug-and-serum group 9.8 per cent. The fatality rates were 11.1 per cent and 14.6 per cent respectively if twenty-four hour deaths were included.

3. In the bacteremic cases the fatality rate was 28.1 per cent with drug alone and 30.0 per cent with drug and serum. If twenty-four hour deaths were included, the fatality rates became 32.8 per cent and 45.3 per cent respectively.

4. In contrasting the results of treatment in the cases treated early with those in cases treated late in the disease, the additional use of serum did not lower the fatality rate in either group.

5. The average response as judged by rapidity of fall in temperature in type I and type II cases was not enhanced by the use of serum.

6. No essential differences were noted in the therapeutic response obtained with the various drugs used—sulfapyridine, sulfathiazole, dextrose sulfapyridine, sodium sulfapyridine, sulfamethylthiazole and sulfadiazine.

7. Of the 78 patients who died, 48 either entered the hospital in a near terminal condition and died within twenty-four hours or had some other severe systemic disease in addition to pneumonia.

8. The present role of serum in pneumonia appears to be its use in the treatment of patients who cannot tolerate the sulfonamide drugs or who do not respond satisfactorily within twenty-four to forty-eight hours to sulfonamide therapy.

BURNS OF THE HAND

DONALD W. MacCOLLUM, M.D.

Associate in Surgery, Harvard University Medical School; Associate
Visiting Surgeon, Children's Hospital; Associate in Plastic
Surgery, Peter Bent Brigham Hospital
BOSTON

As most persons are dependent on the use of their hands for a living, a minor burn of the hands may be a distinct handicap and a major burn a catastrophe. Improperly treated minor burns may easily become major ones, and improperly treated major ones may result in the loss either of the hand or of the life of the patient himself.

The treatment of burns of the hand differs sufficiently from the treatment of burns elsewhere on the body to justify calling particular attention to the difference. In a previous paper¹ the early and late treatment of burns in general was discussed. Certain suggestions made in that paper for treatment of burns of the extremities need to be amplified.

Burns of the hand are caused primarily by explosion, by fire or by contact with hot liquids. The hands of the nonindustrial worker are usually exposed and therefore are more frequently burned than other parts of the body. In the agony of pain and fright the hands are often used to put out flames elsewhere on the patient's own body or on that of some one else. The ungloved hand is obviously more severely burned in instances in which sticky hot liquids or oils are spilled, in which there is a single flash of flame, as in some explosions, or in which momentary exposure to steam occurs. Burns are not often severe if the patient happens to be wearing gloves that can be removed quickly before too deep penetration of the causal agent. Grease-soaked gloves that fit tightly at the wrist and are hard to remove when ignited produce a much deeper burn than would occur if the gloves had not been worn. If hot liquids are spilled over woolen or cotton mittens with knit elastic wristlets, the heat of the liquid is often held in the fabric, resulting in injury to the deeper structures. Since the household mangle has become a popular addition to many home laundries frequent and extremely extensive burns of the hand have been seen. In the latter cases the trauma caused by the crushing

action of the roller complements the trauma from the heat of the ironer.

EARLY TREATMENT OF FRESH BURNS OF THE HAND

The heavy skin on the palmar surface is a natural protective barrier to all injuries, including burns. The dorsum of the hand is likewise toughened to some degree as compared with unexposed portions of the body. However, it is also a corollary that the tougher the hands, the dirtier they are likely to be. Débridement and complete cleansing of burns in the latter group of patients are much more difficult and less certain of success.

Burns of the hands alone are generally less shocking than burns received elsewhere on the body. The patient is more or less accustomed to receiving injuries to his hands, so the element of fright is not as great. Because the hands are exposed, pain from friction of the coverings or clothes on the burned surface is thereby avoided. When the hands are toughened and calloused they are less likely to be as sensitive to pain as some normally unexposed area. If shock does exist, it is to be combated in the usual fashion, with heat to the body, intravenous administration of fluids or transfusion of serum, morphine and the body in the Trendelenburg position. In all cases, pain is enough of a factor to warrant the routine administration of some type of sedative or analgesic.

A good first aid measure is to place the injured hand immediately in a bowl of clean water so that all the burned surfaces are below the water level. The patient will experience pain when the hand is first immersed, but this will quickly be relieved as the air is excluded from it.

After the initial pain and shock have been treated, one proceeds with the treatment of the local area. This should take the form of a careful débridement. All children and hypersensitive adults should be given a general anesthetic for this procedure. In stoical adults with a high threshold for pain adequate analgesia is often obtained with a sufficiently large dose of morphine.

The débridement consists of a thorough cleansing with a solution of 50 per cent green soap and 50 per cent hydrogen peroxide. The finger nails are clipped if they are not to be used for traction (explained later in the paper). All blisters are opened and the raised dead skin is removed. The inside of a raised blister in the hair-bearing areas must be considered as having been contaminated by the dirty surface hairs which were drawn into it as the skin was raised by the fluid formed beneath it. Some surgeons prefer to leave the blisters unbroken in areas not bearing hair, such as the palmar surface. In my experience the ones left unbroken frequently break or go on to infection through small cracks in the macerated surrounding skin. On excessively hairy hands, if the hair has not been burned off it should be removed by extremely careful shaving—even over the burned surfaces. If this is not done the hairs are later enmeshed in either the eschar or the crust that is formed. When the burn heals, the removal of either the crust or the eschar is both hindered and painful if the hairs have been allowed to become caught in it. After being cleansed and debrided, the hand is flushed with physiologic solution of sodium chloride and then soaked in some mild antiseptic solution, such as hexylresorcinol solution or solution of merthiolate. Occasionally a 70 per cent solution of alcohol is used for a final wash, but there are two objections to its use: First, it is extremely painful if the patient is not

From the Department of Surgery, Harvard Medical School, and the Surgical Services of the Children's Hospital and the Peter Bent Brigham Hospital.

1. MacCollum, D. W.: The Early and Late Treatment of Burns in Children, *Am. J. Surg.* 39: 275-311 (Feb.) 1938.

under a general anesthetic and, second, if there are islands of skin that are just barely viable the 70 per cent solution of alcohol may possibly destroy them and thus create a relatively deeper burn.

At this point the operator must decide which of the various medicaments are to be applied to the burned surface while it is healing. One or two generalities may help in such a decision:

1. An eschar of any type is never to be used if either the hand or the fingers are burned on all surfaces. Because the eschar forms a tight, rigid sheath, the subsequent edema beneath it may be big enough to shut off the circulation to the fingers, with resultant gangrene.

2. An eschar of any type is undesirable when movement of the fingers is not able to be controlled, as in young infants or in an epileptic adult. A thin, flexible eschar will stand some movement, but none will be able to withstand motion through 90 to 120 degrees, which may occur with complete flexion of the fingers.

3. An eschar of any type is not to be used if the operator is uncertain of the efficacy of his débridement. Unless he is convinced that he has made the area really clean it is perhaps better judgment to cover the burns

that the débridement need not necessarily be as thorough as when tannic acid is used. The obvious advantage of the gentian violet alone or in combination with the other dyes is this bactericidal action, but unfortunately many surgeons depend too much on this quality

Fig. 2 (case 2).—Burns of the fingers from boiling water treated with tannic acid jelly. Eschars were produced which tightened with the subsequent edema so as to result in gangrene of the ends of the index, middle and ring fingers. It was felt that the burns were of no more than second degree and that the loss of the fingers was preventable.

and fail to carry out a proper initial débridement. The result is an infected burn draining lavender pus. The penetrating staining quality of the dyes constitutes a definite drawback to their use in a ward other than one for the treatment of burns where discoloration of the linen and furniture is of some importance.

It may be stated without reservation that if a proper cleansing is first carried out the end result will not be affected by the type of eschar applied to the burn, provided all procedures are done gently and the area is kept sterile and immobilized until healing is maximum. If the latter principles are followed to the letter it should not be considered the fault of the eschar if

Fig. 1 (case 1).—Complete burn of the right hand (from contact with stove) treated with tannic acid eschars on all surfaces. Burns were not kept sterile, so the combination of infection and gangrene from constriction of the eschars at the finger tips resulted in loss of a part of the thumb and all fingers with the exception of the index finger.

with sheets of tulle gras² over which are placed gauze sponges soaked in a mild antiseptic.

If an eschar is to be used the operator has several varieties from which to choose. The most common ones are those formed by tannic acid alone or in combination with silver nitrate, by gentian violet alone or in combination with crystal violet and brilliant green or by wax, ferric chloride or iodine. When tannic acid alone is used a 2.5 per cent solution is sprayed on the burned surfaces at frequent intervals (every thirty to sixty minutes for about twenty-four hours). This may be varied by applying a 5 per cent solution of tannic acid followed in ten to fifteen minutes with a solution of 10 per cent silver nitrate, producing an immediate and permanent eschar. If the latter combination is used, it is to be emphasized that after the initial administration no further application of either tannic acid or silver nitrate is to be carried out or the eschar will become too thick. Gentian violet in a 2 per cent aqueous solution, either alone or in combination with brilliant green and crystal violet, has a definite bactericidal effect, so

Fig. 3 (case 2).—Appearance after ends of the fingers dropped off, leaving raw surfaces on the dorsum still unhealed.

a raw surface still remains, for it denotes destruction by the burn of all the layers of the skin with or without involvement of deeper tissues. If the raw area is large it will be necessary for epithelization to proceed from the periphery, and the resultant scarification in a region as mobile as the hand will cause contractures and

2. A wide mesh gauze impregnated with petrolatum, compound tincture of benzoin and Peruvian balsam, sterilized in an autoclave for fifteen minutes under 20 pounds of pressure.

deformities. It naturally follows that further plastic procedures to restore this lost tissue will then be required.

It must be emphasized that to be effective an eschar must be kept as immobile, as dry and as sterile as possible. However, bandages and splints cannot be applied over the eschar or it will become moist and macerate. To keep the burn dry and sterile, the hand is placed in a heated cradle that is covered with sterile sheets. To keep down edema, the hand should be elevated well above body level. To keep the fingers immobilized, it is advisable to pass sterile rubber bands or fine steel wires through each finger nail and attach them to the ring of a banjo splint. Little force is able to be applied to these traction lines, for they soon tear or cut through the nail. They serve merely as check-reins to remind the patient to keep the fingers quiet and in extension. Consequently, a cooperative, intelligent patient is the first prerequisite when this method

below the age of 5 years and all patients above this age who are of below average intelligence, or if the burns completely encircle the fingers the use of an eschar is not advisable. In the uncooperative group, motion will destroy and crack the eschar, leaving portals of entry for possible infection of the burn beneath. In the group with total burns the eschars, if tight, may act as tourniquets. Consequently, some type of ointment should be employed as a dressing if either of these situations exists. This is to be followed by careful bandaging of each finger (no matter how small) as a separate unit and firm attachment of all fingers, hand, wrist and arm to a splint for immobilization. This method presupposes that the operator realizes (1) that fluid is going to be lost from the burn in large quantities, (2) that he must be equipped to recognize the rate of loss of serum by studies of the blood and serum protein, (3) that he will be able to carry out the replacement of this serum by transfusions of blood or of blood plasma

Fig. 4 (case 3).—Third degree burns of the fingers from boiling water. Burns were debrided and treated with sterile ointments. Burn completely encircles each finger.

of treatment is employed. Some surgeons advise the insertion of straight needles through the distal phalanges similar to small Kirschner wires, for traction. These are to be recommended only if one can be absolutely certain of initial and continued sterility in the region of the insertions of the needles during the time of healing.

Healing of areas of first and second degree burns will be indicated when the eschar becomes dry and separates from its base. The separated portions should be removed with sterile forceps and scissors, with care not to expose any raw surfaces by being too rough or by being overenthusiastic about the eschar's early removal. Small areas of third degree burn will continue to heal from their peripheries under the eschar, which will finally loosen and drop off. Over large areas of third degree burn the eschar will remain tightly adherent for a longer period, during which time healing still goes on. Finally it will become softened and should then be removed, exposing the granulations beneath it.

Again it must be pointed out that if the patient is not of the cooperative type, and this includes all children

as the situation indicates, (4) that he must carry out the most rigid aseptic technic in dressing and nursing care to prevent contamination and (5) that he must do all this with the utmost gentleness, both to avoid pain to the patient during the changes of dressings and to avoid injury to the burn itself.

It has been found that if an ointment is to be applied to the hand it must first of all be sterile. It is preferable to have this ointment impregnated in strips of gauze so that it can be bound about each finger rather than to attempt to spread grease over a slippery, raw surface to which it does not readily stick. In addition, if the gauze has a wide, open mesh, it allows both serum to escape and antiseptics to reach the burn. Strips of tulle gras meet these two requirements. Over the tulle gras may be placed strips of regulation type surgical gauze which are either dry or soaked in a mild antiseptic. My choice of antiseptic is usually one of three: hexylresorcinol solution, solution of merthiolate or a mixture of alkyl-dimethylbenzyl ammonium chlorides.

To do an adequate dressing to a hand, it is necessary for the operator to scrub his hands and put on sterile

rubber gloves rather than attempt accurate placement of the dressing with sterile instruments. In this way he is also able to control the movements of the fingers and hold parts of the dressing in place while the rest of it is being applied. No two raw surfaces are to be allowed to come in apposition. Therefore, each finger requires a separate dressing. A padded basswood board cut to fit the hand and each finger is usually used for immobilization, the hand being fixed to it with narrow elastic adhesive (elastoplast) and covered with elastic bandage and stockinet to keep the elastic bandage from becoming displaced. The hand, wrist and arm are included in this splinting. If it is possible, the tip of one unburned finger should be left exposed so that the circulation may be checked. When a finger is left exposed and is to be tested for blanching, it is to be remembered that the tip should be touched with a sterile instrument rather than with the nurse's or physician's unsterile hands. If all fingers have been burned and it is impossible to leave any exposed, great care and constant attention must be paid to the application of the

First and second degree burns should heal within ten to fourteen days. Areas of third degree burn, if small, will continue to heal from the periphery of each raw island, provided the dressings are applied tightly enough to keep the granulations flattened. Large areas of third degree burn will require replacement of tissue from some other site to prevent contractures.

LATE TREATMENT OF BURNS OF THE HAND

If the patient fails to come under medical supervision until several days or weeks after the injury, the primary efforts should be directed toward getting the burn as clean as possible. This should not be done by an operative débridement because of the danger of breaking down local resistance in what is certain to be an infected field. Soaks daily or twice daily in a mild, warm antiseptic solution followed again by dressings of tulle gras are my regimen of choice. Over the tulle gras are placed sponges wet in diluted solution of sodium hypochlorite, chloramine-T or eusol, and over this a dressing identical to that previously described. After a week to ten days of this regimen the raw areas will usually be in condition for grafting.

GRAFTS

Whether the burns have healed with obvious contractures or whether raw areas still remain to be healed, a fundamental evaluation now must be made of exactly how deep the scarification has been or will be. Dependent on this decision is the type of graft that will be employed for the best functional and cosmetic result. In all other areas of the body if healing is allowed to continue without grafting, contracting bands of heavy scar tissue may develop, may tighten and with exercise and massage may loosen sufficiently so that replacement of skin or subcutaneous tissue is not found to be necessary. In either the hand or the

Fig. 5 (case 3).—Result after cleansing over a period of fourteen days and covering the defects with thick razor grafts.

bandage. This is of particular importance to the surgeon who usually treats adults and who finds himself bandaging the fingers of a 6 month old baby. The hand is elevated above the level of the rest of the body by placing the splint on a heavy block pillow and protecting the area from the weight of the bedclothes.

The dressings are to be changed once every forty-eight hours, or oftener if the exudation of serum is sufficient to soak through to the outside. Once the outer dressing is discovered to be wet, the burn has been theoretically contaminated by retrograde bacterial action in a moist field. Too frequent dressings may be injurious to the burn and may slow up healing. The frequency of change, therefore, becomes a matter of nice judgment and is able to be regulated only by the patient's progress.

Removal of the bandages and outer sponges can always be accomplished without pain to the patient. The removal of the layers next to the burn is best effected after the hand has been soaked in a sterile saline solution for five to ten minutes. After this length of time the creation of a current in the basin by means of a sterile paddle frequently removes the remainder. In this way the burn is washed thoroughly and there has been the minimum of disturbance to the healing edges.

foot the same sequence is more likely to result in a permanent contracture without the subsequent relaxation, due primarily to a persistent shortening of muscles, tendons and tendon sheaths, even though they may not have been involved in the burn. It is therefore necessary to prevent the formation of these contractures by early grafting or, if they have occurred, to correct the deformity as soon after healing has taken place as it is possible.

Every effort should be employed to cleanse the hand thoroughly before operation. If one is dealing with a completely healed but scarred, contracted hand several scrubbings with soap and water reaching all the folds and crevices should be carried out during the forty-eight hours preceding repair. The common procedure of wrapping or bandaging the hand after these preoperative scrubbings is to be avoided, because usually this causes the hand to perspire, thereby actually raising the bacterial count. Obviously, prevention of gross contamination such as would occur with normal work is to be avoided.

At the time of operation the hand is again prepared with soap and water, ether and alcohol. Antiseptics that stain the skin are to be avoided, for it may be impos-

sible to make a decision of questionable viability of a flap if it has previously been discolored with a dye. A blood pressure cuff may be placed on the arm, loosely enough so that it will not hinder venous return. The cuff may be inflated then as an emergency tourniquet at any time during the operation. The use of a tourniquet throughout the operation is not advised, because in the bloodless hand it is sometimes difficult to distinguish scar tissue from normal fascial layers. The ischemia of small blood vessels and subsequent edema which follows removal of the tourniquet will also jeopardize the take of any graft. It is essential that all bleeding be controlled either by hot-pressure packs or by crushing the ends of the vessels and that ligatures be conserved for as few of the larger vessels as possible.

It is vital that not "just enough" scar tissue be removed to relax the contractures but that all of it be removed. If a deep scar is left the graft over it will become wrinkled and the function of the hand or digits will be impaired. If the tendon sheaths or tendons are

Fig. 6 (case 3).—Splint that was worn by patient for a period of six months after grafting.

fascia lata. If only a short segment of the tendon is destroyed it is possible to lengthen the tendon at this time by any of the usual operations for lengthening tendons anywhere. It is a wise precaution to leave a window in the sheath over the point of suture of the tendon because motion of the finger cannot be carried out until several days after operation, if the graft over it is to be saved. Adhesions between the operative site in the tendon and the fat of the graft are easier to break than those which would form between tendon and tendon sheath if no window had been left.

Now that all scar tissue has been removed, bleeding controlled and as much motion as possible restored to the hand and fingers it is necessary to employ some type of graft to cover the defect.

In all grafts to the hand, skin with or without subcutaneous tissue must be brought from some other site and placed where it must withstand a good deal of wear, and it must be as inconspicuous as possible. It is to be remembered that skin taken from the abdomen or leg or any other site and placed on the hand will

never take on the characteristics of the true skin of the hand. The skin itself, whether it is on a free graft without fat or on a pedicle containing a subcuticular panniculus, has, and always will have, essentially the same characteristics as that on the site from which it

Fig. 7. (case 4).—A, scar contracture of the hand in a girl aged 2 years, the result of a third degree burn of the palmar aspect of the hand and all fingers but the index finger. Note the lack of extension of the fingers and extreme adduction of the thumb from the scarred hands. B, result eighteen months after the scar had been dissected out and one large unperforated thick razor graft had been applied. All fingers and the thumb have an absolutely normal range of mobility, and the graft matches the surrounding tissue very well.

came. It has been frequently stated that skin grafted to the hand or the foot should always be accompanied by a layer of fat and subcutaneous tissue so that a pad will be formed to withstand trauma and prevent the new skin from breaking down. This is not always correct. If only the skin of the hand, either the back or the palm, has been destroyed and there remains after dissection of either the scar or the raw, unhealed area

Fig. 8 (case 8).—Heavy scarring from a fourth degree burn received three years before these pictures were taken.

the normal fatty pad of the hand, it is necessary to replace the destroyed skin only by a free graft without fat. If, however, the fatty pad has been destroyed or the scar extends deeply enough to involve the fascia, tendon sheaths or tendons, then without question the

graft of choice is some type of pedicle containing the required amount of subcutaneous tissue.

If a free graft is to be used the recipient site must be even and firm, without foreign bodies such as sloughing tissue, bits of suture material and hematomas.

Fig. 9 (case 8).—After dissection of all scar tissue including tendon sheaths, the hand was placed in a pocket on the inner side of the thigh. The donor area was covered at the same time by cutting thick razor grafts and gluing them to the back of the hand so that they would be in apposition with the raw surface as the pedicle was attaching itself to the palmar side.

Either a thick razor graft or a full thickness graft more nearly imitates the thickness of the normal skin of the hand. Whichever one is used, there is little difference in the end result, provided it is done properly. The choice usually is dependent on which one the surgeon

uses varying greatly with each surgeon. I have found an effective dressing to be strips of tulle gras applied over all grafted surfaces, over which are placed narrow sponges soaked in a 1:5,000 solution of acriflavine hydrochloride. These sponges help to prevent moisture, maceration and subsequent infection in an area which perspires easily. They are covered by dry gauze, narrow strips of elastic adhesive (elastoplast), Ace bandage and stockinet. The hand, wrist and arm are then fixed to a light wooden splint by adhesive tape and bandages.

The dressing is usually left undisturbed until the seventh or eighth postoperative day. It is then carefully removed and a dressing identical to the first one reapplied except for the omission of the sponges soaked in acriflavine hydrochloride. In two to three weeks after operation the graft will be ready for exposure to the air, gentle massage and both active and passive motion. By far the most important element in the proper postoperative care of free grafts to the hand is the realization that unless the fingers are adequately splinted for at least six months distressing contractures of the graft will inevitably take place. The resultant deformity of the fingers is hard to overcome once the contractures have been allowed to occur. To avoid this, patients with such grafts are put on a regimen of stretching, exercise and massage for two to three periods a day, none of which last any longer than thirty to forty-five minutes. For the remainder of the time the hand is splinted as shown in figures 6 and 11. At the end of six months the hand is allowed out of the splint during the day but at night is confined again in the splint over a period of an additional six months or more. Numerous examples of failure of adequate post-

Fig. 10 (case 8).—Result one year after the pedicle had been placed on the hand. Note the interdigital webs, which were purposely left. Note also the thickness of the pedicle flap.

can handle with the best result. In order to prevent maceration and slow healing at the periphery, it is essential that the graft match the defect absolutely without overlapping on the normal skin. To prevent displacement of the new skin when the dressing is applied, it is advisable to suture it evenly to the edges of the raw surface. A dressing is then applied, the type of mate-

operative splinting have been seen. Once secondary contractures have occurred an attempt can be made to straighten the fingers by a vigorous regimen of physical therapy, but frequently a second operative procedure will be necessary. The second procedure can seldom take the form of a free graft because too much of the subcutaneous fat will need to be removed in order to

relieve the contractures again. Necessarily, a thin pedicle graft is usually employed with good result.

Whenever a pedicle graft is to be used, whether it is one with a single or a double hinge, open or tubed, the donor site must be chosen with care. Although the usual donor sites are the abdomen, buttocks or thighs, it is important that the operator plan to attach the hand to the site in such a fashion that the hand, wrist, elbow and shoulder are in neutral positions during the period of healing, which lasts two to three weeks. If distortion of any part is allowed the patient will be violently uncomfortable, squirm about in the dressing to ease muscular cramps, pull on the pedicle and destroy the graft.

After complete dissection and preparation of the base similar to that described previously, a pattern of the defect is first marked and cut out of muslin with an extension on one side to represent the pedicle or hinge. It is important for this hinge to be as wide as any portion of the flap to be raised. With the pattern held tightly to the recipient site the hand is moved to the position over the donor site that it will occupy during the period of healing. The edge of the hinge of the pattern is next transferred and held tightly to the donor site. The hand is then drawn away, allowing the pattern to fall flatly into position on the donor site. The design of the cloth pattern is next transferred to skin by marking around it with sterile ink. In choosing the site for the hinge it must also be remembered that the main blood vessels and lymphatics should preferably run parallel with the long axis of the flap. It is occasionally necessary to disregard this last precaution, but whenever it is disregarded the safety of the procedure is less insured.

The flap is then raised carefully and gently, so that no portions will be destroyed by unnecessary trauma in a site at which the blood supply, by the very nature of the operation, will be impaired. The flap is sewn to the hand with interrupted sutures both to the subcutaneous layers and to the skin. The site left raw by raising the flap and pedicle then may be closed by undercutting or by razor grafts from some other site (fig. 9). At the end of an interval varying from two to three weeks and dependent on how well the flap has become attached to its new site, the hinge is cut. If the hinge is wide and it is felt that the new circulation is not

yet adequate, the detachment may be carried out in two or more stages. If there has been an error in measurement of the flap the pedicle can be utilized to fill the defect. If the pedicle is not needed it may be returned to its original site and sutured there.

Fig. 12 (case 8).—Result eighteen months after the pedicle had been placed on the hand. The thickness has decreased considerably and matching of color is nearly normal.

Fig. 11 (case 8).—The webs were released and the hand splinted again for six months except for physical therapy and intervals of active and passive motion.

When the hinge to a flap that is to cover the palmar surfaces of both fingers and the hand lies along the side of the hand (fig. 9 A), it will be impossible to produce, at this first step, normal interdigital webs without interrupting the supply of blood to the distal portions of the flap. Therefore webs are purposely formed (fig. 10) and are released as a secondary procedure (fig. 12).

The postoperative care of the pedicle flap is of less concern than that of the free graft to the hand. The new flap is usually much too thick, rather soft and covered with hair or down. In fact, to shake hands with a person who has had a pedicle flap grafted to the palm has been imaginatively likened to shaking hands with a mouse! It is wise to splint the hand for a period of at least three to four months so that contractures will not develop along the lines where the flap joins the normal skin. If these lines of junction are along flexor surfaces of the finger it is wise to extend this period of splinting to six months and carry out the same routine as that advocated for free grafts. If the lines of junction are on extensor surfaces the normal movement of the hands will keep them well stretched and splinting will not need to be as protracted. As time goes on and the hand is used, the thickness of the flap diminishes considerably and the soft spongy feeling of the pedicle decreases but never completely disappears. With proper planning the functional and cosmetic result can be excellent.

CONCLUSIONS

The treatment of burns of the hand differs from the treatment of burns elsewhere on the body. An eschar can be used but only on hands that have not been burned completely. In complete burns an ointment should be used, accompanied by a rigid program of cleanliness and the systemic replacement of the fluid lost from the injured area. When the burns have not healed or there have been contractures from scarring, it is necessary first to diagnose exactly what tissue has been lost and to replace this loss with a similar type of tissue. Specific details outlined for the application of grafts to the hand have proved satisfactory both from a functional and from a cosmetic standpoint.

FROZEN AND DRIED PLASMA FOR
CIVIL AND MILITARY USE

MAX M. STRUMIA, M.D.

AND

JOHN J. McGRAW, M.D.

BRYN MAWR, PA.

Recent experimental and clinical observations have definitely established the value of plasma as a substitute for whole blood in many clinical conditions.¹ The use of plasma in place of whole blood is suggested by two independent lines of thought. The first is a critical appraisal of the clinical indications for blood transfusion based on the physiologic action of each one of its components; the second is a matter of technical convenience concerned mostly with the problems of preservation and administration.

We will consider these two elements separately and briefly.

CLINICAL CONSIDERATIONS

The accompanying table lists what we consider at present the indications for the use of plasma in place of whole blood as well as the conditions in which the use of whole blood is recommended.

From the clinical standpoint it is also most essential to bear in mind that plasma properly prepared offers the following advantages:

1. There is freedom from reactions, with the exception of relatively rare instances of mild urticaria, while whole blood transfusion carries with it a small but constant risk of severe and even fatal complications.²

2. Plasma may be given in much larger quantities and in repeated doses.

From the Clinical Laboratory, Bryn Mawr Hospital.

This work was aided by a fund created by Mrs. John S. Sharpe, Mrs. Edward Law, the Women's Board and the Social Service Department of the Bryn Mawr Hospital.

3. Plasma lends itself to concentration, if this is considered desirable.

4. Plasma does not add to hemoconcentration.

As the advantages of plasma over whole blood have become recognized, it is interesting to note the decrease in the number of whole blood transfusions as a result of the increased use of plasma. The chart indicates this tendency at the Bryn Mawr Hospital in the past three years. The number of patients annually admitted to the hospital during this time has increased from 5,214 to 5,487 and, while the number of blood donors has practically doubled, the number of whole blood transfusions has actually decreased.

The discrepancy between the total number of donors and the sum of whole blood and plasma transfusions as appears in the chart is due to the fact that the major-

Indications for Plasma and/or Whole Blood Transfusions

1. Shock.....	{ With little or no hemorrhage With severe hemorrhage	Plasma Plasma for immediate relief, followed by whole blood if warranted
2. Burns.....	Plasma; whole blood contraindicated because of hemoconcentration
3. Infections.....	As a means to supply specific and nonspecific immune bodies	Plasma, supplemented by whole blood when severe anemia is present
4. Hypoproteinemias	Nutritional, hepatic, nephrotic and from various other causes	Plasma
5. Cerebral edema..	Such as accompanies injuries, toxemias, and so on	Plasma in concentrated form
6. Blood dyscrasias	{ Such as those with hemolytic tendencies, those with low prothrombin content, hemophilia, and so on Particularly those with hemorrhagic tendencies, such as certain forms of purpura	Plasma Whole blood
7. Anemias.....	As palliative in various hypoplastic forms	Whole blood; plasma indicated in the chronic forms of hypoproteinemic anemias
8. Acute poisonings	Affecting the oxygen carrying capacity of hemoglobin, such as carbon monoxide	Whole blood

ity of the plasma transfusions in the past two years have totaled 500 cc. This amount requires, on the average, the blood of two donors.

TECHNICAL CONSIDERATIONS

For a more complete understanding of the advantages offered by plasma, it is necessary to have a knowledge of the possibilities and limitations concerning preparation, preservation and administration of both whole blood and plasma. These may be summarized briefly as follows:

1. Whole blood has a limited and relatively short period of preservation.

2. Transportation of whole blood beyond short distances involves considerable difficulty because of the need of relatively constant refrigeration temperature, which can be obtained only with the use of heavy and bulky apparatus.

3. Whole blood needs to be typed and cross matched before administration.

4. Whole blood, if preserved more than a few hours after collection, requires filtration before administration.

On the other hand,

1. Plasma may be preserved for an indefinite period of time.
2. It is easily transported under adverse conditions when suitably prepared.
3. It does not need to be typed prior to administration if properly pooled or diluted, thus being immediately available for use in emergencies. Errors in blood matching due to hurried procedures are thus also eliminated.
4. Proper preservation (frozen or dried) prevents fibrin precipitation and renders filtration unnecessary.

The question of the use of plasma versus serum has been unduly magnified and often misunderstood. While we agree on the similarity of certain therapeutic actions of plasma and serum,³ we continue to give preference to plasma for the following reasons:

1. A greater yield of the fluid phase may be obtained by separation of plasma if centrifugation is employed.
2. Production of plasma may be coordinated with the functioning of a blood bank.
3. Reactions to administration of properly preserved plasma are unknown, save for the rare mild urticaria mentioned before.

A disadvantage of citrated plasma that has been often pointed out is that it cannot be conveniently filtered through a Seitz or similar filter for purpose of sterilization because of clotting. Such filtration, however, is made entirely unnecessary by the adoption of a closed system for the collection, separation, pooling and distribution of plasma, by reducing to a minimum the time required by these operations, and by adequate checks on the sterility and toxic properties of plasma by means of cultural studies and inoculation of material into mice.^{4b} The addition of merthiolate 1:10,000 may or may not be used as a further precaution against contamination. There remains another and more valid objection to plasma, namely that on standing fibrinogen and possibly also a globulin fraction precipitate out, forming a flocculent or granular material which must be filtered out before administration. The elimination of this difficulty is to be found in the rapid fixation of fibrinogen as well as of other labile elements by freezing immediately after separation and pooling, followed or not by drying from the frozen state. Obviously the plasma must be free of precipitate before fixation. This is always the case when plasma is drawn off immediately after centrifugation.

PRESERVATION AND STORAGE OF PLASMA IN THE LIQUID STATE

Keeping of plasma in the liquid state at 4 C. had been employed at the Bryn Mawr Hospital since 1931 as the principal means of preservation. More recently five severe pyrogenic reactions, following the adminis-

tration of plasma from a lot later proved to be contaminated, emphasized the dangers of this means of preservation:

CASE 1.—M. J., a woman aged 81, was operated on for removal of a carcinoma of the colon and cecostomy. On Sept. 26, 1940 intravenous administration of plasma was resorted to for correction of hypoproteinemia. After 200 cc. of pooled citrated plasma diluted with equal parts of saline solution had been administered, the patient had a severe chill followed by a temperature rise to 103 F. The plasma transfusion was immediately discontinued and the temperature returned to normal in two hours.

CASE 2.—H. C., a man aged 74, was operated on for relief of obstruction from peptic ulcer by gastrojejunostomy. On Oct. 4, 1940 transfusion of pooled plasma for correction of hypoproteinemia was resorted to. After receiving 200 cc. of a scheduled 500 cc. transfusion, the patient had a chill followed by temperature rise to 103 F. The temperature returned to normal in two hours.

CASE 3.—C. W., a man aged 65 suffering from anasarca associated with hypoproteinemia in the course of hypertensive heart disease, received on Oct. 3, 1940 80 cc. of pooled plasma regenerated from the dried state and concentrated four times. This material had been prepared from the same lot of citrated plasma used in the previous cases. The administration was followed by a chill and temperature rise to 101 F. The temperature returned to normal in four hours.

CASE 4.—C. S., a woman aged 35, was operated on for relief of intestinal obstruction caused by adhesions. A transfusion of pooled citrated plasma was resorted to on Oct. 4, 1940, immediately after the operation, for prophylactic

treatment of impending shock. Within fifteen minutes from the beginning of the transfusion, when less than 100 cc. had been administered, the patient had a severe chill, with a temperature rise to 105 F. The fever persisted for four hours. Two days later the patient was given 200 cc. of citrated pooled plasma from the same lot. This administration was followed in thirty minutes by a chill and temperature rise to 103 F. The temperature returned to normal in four hours.

The plasma used in the cases reported had been pooled from several lots of citrated blood, which had been preserved at 4 C. for a period of about five days. Merthiolate 1:10,000 had been added immediately after pooling, but no bacteriologic studies were made at that time.

Because of the long favorable previous experience with liquid plasma, it was at first thought possible that the reactions observed were due to a break in the proper technic in the preparation of glassware and rubber tubing. Consequently, as noted, a second dose of the same material was given to patient 4 after a rigorous check in the technic of administration and after cultures of the material had shown no growth. The possibility of an abnormally high isoelectrolytic titer had also been ruled out. At this time centrifugation at high speed of 10 cc. of the plasma in question showed large num-

(d) Drying of Plasma by Low Temperature Condensation in Vacuo, June 1941.

bers of gram-positive bacilli, approximately 1 by 3 microns without spores, and square ended. Sediment containing large numbers of these organisms was cultured aerobically and anaerobically repeatedly, but no growth could be obtained.

Similar reactions have been observed by others⁵ and suggested further studies on more adequate means of preservation.

The addition of merthiolate in proportion of 1:10,000 does not completely eliminate the danger of reaction from contamination, particularly when the plasma is separated from citrated blood which has been stored for a number of days in a blood bank. In addition to the danger of bacterial growth, it has been definitely demonstrated that prothrombin, complement and fibrinogen deteriorate considerably in liquid plasma stored at 4 C. It is possible to obtain plasma which is low in fibrinogen by permitting precipitation and settling in citrated blood allowed to stand many days before separation. This is a method widely used when blood plasma is prepared solely as a by-product of blood banks.⁶ The disadvantages are similar to those associated with the storage of liquid plasma at 4 C.

The addition of calcium chloride to plasma to eliminate fibrinogen has been proposed.⁷ This additional procedure is unnecessary if immediate fixation of fibrinogen by freezing is resorted to.

Summarizing, the storage of citrated plasma in the liquid state has been found to be undesirable because:

1. It is dangerous from the standpoint of ease of bacterial contamination, with development of pyrogenic substances.
2. It allows deterioration with loss of prothrombin, complement and fibrinogen, the latter forming a precipitate which must be removed before use.

PRESERVATION AND STORAGE OF PLASMA IN THE FROZEN STATE

As far back as 1932 it was noted that some of the more labile properties of plasma could be effectively preserved by keeping it in the frozen state, and that with certain precautions frozen plasma could be thawed out and used intravenously in human beings without adverse reactions.⁸ More recently, additional studies have definitely proved that it is practical to keep plasma in the frozen state for several months and probably much longer without significant deterioration of prothrombin, fibrinogen, complement or the specific antibodies.

Freezing of plasma and keeping it in the frozen state as a means of preservation is offered as the method of choice, meeting the essential requirements in the greatest number of instances.¹⁰

The advantages of frozen plasma are that:

1. It is easily prepared.
2. It is economical.
3. It is easily stored and transported because of the wide range of the temperature of preservation as long as it remains frozen.
4. It retains its content of the most labile elements, such as prothrombin, without significant losses and remains sterile.

5. It does not require addition of water for restoration, as opposed to dried plasma.

6. It is clear and ready for administration without filtration when properly thawed.

Briefly the essential technical points are:

1. Fairly rapid freezing, requiring not more than three to six hours.
2. Maintenance in storage at a safe level below freezing.
3. Rapid thawing and warming to room temperature in the water bath at +37 C. with occasional gentle agitation. This operation should not require more than twenty-five minutes.

Plasma preserved by freezing, maintained in the frozen state and properly thawed results in a clear product indistinguishable in appearance from the original fluid. At present, all the plasma at the Bryn Mawr Hospital is preserved by freezing with the exception of a small amount which is dried from the frozen state. The adoption of routine preservation of plasma by maintenance in the frozen state has been justified by its safety and efficacy proved on numerous administrations over a period of six months. Serum may be properly stored by the same procedure.

DRIED PLASMA

Plasma dried from the frozen state has definitely been shown to be a dependable material, free of reactions and convenient for rapid restoration and administration. The advantages of dried plasma over frozen plasma are that:

1. It can be preserved and transported under all conditions of temperature without refrigeration.
2. It can be regenerated for administration in a short period of time under adverse conditions.
3. If indicated, it lends itself to administration in a concentrated form.

Dried plasma has been lately featured in many reports. Many new methods have been proposed for the drying of biologic substances.⁹ There has been the tendency, in many instances, to consider drying of plasma as the best means of preservation. The advantages of preservation of plasma by keeping it in the frozen state and by drying have just been mentioned. Proper drying of plasma is at best a difficult and expensive procedure. It seems, therefore, useless to remove water from all plasma only to add it again when freezing is a method of preservation as good, and even better in most instances, and has the advantages of simplicity and economy. A critical comparison shows that the two methods have different

fields of application and that maximal benefit can be derived by the judicious selection of the one best suited for the needs.

Since, without doubt, the best methods of drying are from the frozen state, this suggests at once the possibility of combining the two means of preservation, whereupon plasma immediately after collection and pooling is frozen in a suitable container^{4c} and kept in the frozen state. It may be then thawed and used, or, as the need and opportunity arises, dried from the frozen state.^{4d} It may at this point be stated that drying of plasma with units of small capacity, such as would fit the needs of the average size institution, is neither practical nor economical.

It may also be stated that, for a hospital, drying of plasma is not necessary except for the already mentioned instances when administration of concentrated plasma is necessary or in rare cases of extreme emergency, when even a few minutes count. In this respect it is to be noted that it takes from two to five minutes to dissolve plasma dried from the frozen state, while it takes about twenty minutes to thaw frozen plasma.

For the average institution, keeping of plasma frozen at temperatures of -10°C . or below is made practical and economical by a number of low temperature cabinets now on the market.

Even when large quantities and long distances are involved, the use of frozen plasma will in most instances constitute the method of choice for the preservation and distribution of the largest bulk of the material. This has been made practical of late by the great popularity of frozen food and therefore by the vastly improved facilities for low temperature storage, transportation and distribution, particularly by properly refrigerated trucks. The same considerations apply for ships at sea when they are equipped with facilities for the keeping of frozen food.

Frozen plasma, when rapidly thawed out and warmed to room temperature, may be kept in the liquid state without fibrinogen precipitation for at least several days. This suggests another simple and effective means of transportation and distribution. For example, plasma on request for use within twenty-four hours could be properly thawed out at the place of storage and then delivered in the liquid state and ready for immediate administration. Air transportation greatly increases the radius of useful and practical distribution. Beyond the period of forty-eight hours thawed out frozen plasma may be used, but filtration to remove fibrin may be necessary.

The legitimate field of usefulness of dried plasma in addition to the clinical conditions requiring plasma in concentrated form is in cases of adverse conditions of storage and transportation, such as may prevail in isolated areas not provided with means for keeping frozen plasma or too far to be provided by rapid transportation.

Dried plasma also serves a purpose of capital importance in furnishing a small reserve of material available for immediate use to units that may later on be provided with frozen plasma if the need for larger quantity arises.

The routine use of concentrated plasma in the treatment of shock¹⁰ does not appear justified by (1) the acknowledged fact that, regardless of the initiating

factor, the essential lesion in shock is a decrease in volume of circulating blood; (2) our own experience; ¹¹ (3) the experience of British workers.⁵ The notable exception is that of shock with severe head injuries.

UNITS FOR THE PREPARATION OF PLASMA

From the foregoing considerations it appears desirable that each medical institution of sufficient size should be provided with means for the collection of blood, the separation, pooling and freezing of plasma and a means of maintaining plasma frozen at a temperature of -10°C . or below. It is estimated that preservation of plasma in the frozen state would take care of at least 90 per cent of the needs of all institutions. The remainder of the plasma should be made available preserved in the dry form, for the purpose of concentration, for emergency cases requiring instantaneous restoration and for supplying the rare extrahospital cases when, because of various conditions, frozen or recently thawed plasma cannot be properly supplied.

For their needs of dried plasma, most institutions may either depend on apparatus of small capacity or partake of a cooperative plan whereby dried plasma is prepared in institutions provided with larger apparatus and properly trained personnel. The latter plan is by far the most desirable because of obvious technical and economic reasons. It requires considerable skill and supervision for the proper operation of a drying apparatus such as that used for drying in vacuo from the frozen state by condensation.^{4d} In addition, particularly if mechanical refrigeration is employed, it costs much less per dose of plasma to dry in an apparatus of large capacity.

We thus come to consider (a) the majority of hospitals, where blood may be collected by a standardized method, plasma separated, pooled, frozen and kept in the frozen state, and (b) a smaller number of hospitals performing the same operations but on a larger scale and which in addition are equipped for the drying of plasma in large quantities, in the order of 25 to 50 liters weekly. These hospitals would act as "drying units" and provide the smaller hospitals with desiccated plasma.

The material to be dried can be transported to the "drying units" best as fresh citrated whole blood, preferably in a sufficient number of bleedings to make a suitable pool, usually ten. The material may also be transferred as fresh pooled liquid plasma or as frozen plasma in containers suited for drying.

When the material is delivered to the large drying unit as whole blood, the responsibility for separation, pooling, distribution in the final containers and sterility checks lies with the drying unit. The responsibility for the serologic studies for syphilis may be assumed by either the collecting or the processing unit. This exchange of containers and material between the collecting unit and the drying unit is made easy by the standardization of the apparatus and procedure for the collection, separation, distribution and preservation of plasma. A type of standardized apparatus and procedure has been offered.⁴ This procedure features an 850 cc. cylindric bottle for the collection and centrifugation of citrated blood in the original container, separation, pooling and distribution of plasma by a closed method, followed by freezing and/or drying in standard receptacles.

10. Hill, J. M.; Muirhead, E. E.; Ashworth, C. T., and Tigertt, W. L.: Use of Desiccated Plasma, *J. A. M. A.* **116**: 395 (Feb. 1) 1941.

11. Strumia, M. M.; Wagner, J. A., and Monaghan, J. F.: The Use of Citrated Plasma in the Treatment of Secondary Shock, *J. A. M. A.* **114**: 1337 (April 6) 1940.

This bottle, as well as most of the other apparatus used in this procedure, is from stock material. The only improvement which appears desirable at this time after several months' experience is the construction of a similar but smaller bottle, of a capacity of 650 cc., on the assumption that it would fit a smaller and hence less expensive centrifuge.

A large "drying unit" following this standardized procedure would have a capacity sufficient to serve twenty to forty average size hospitals. By limiting to about half the number of institutions served there would be a reserve capacity which could be used for the drying of plasma in cases of local or national emergencies.

THE NATIONAL PREPAREDNESS PROGRAM AND THE SUPPLY OF PLASMA

While the methods of preparation and preservation of plasma and the institution of cooperative units for the drying of plasma just mentioned are essentially planned for use in civil life, they lend themselves well to supply the community in cases of local emergencies or the American Red Cross or the Army and Navy Medical Corps in case of national emergency.

This may be readily accomplished by the organization of many units for the collection of citrated blood preferably located in hospitals already having experience in this work. Once collected, the citrated blood from various units is immediately transferred to the nearest larger unit previously referred to as a "drying unit." There, plasma is separated by centrifugation, pooled, distributed in the final containers and frozen. Responsibility for serologic tests for syphilis as well as sterility and toxicity tests rests with the larger units. They also see to the preparation of the blood collecting apparatus and provide the technical supervision for the smaller or collecting units.

The plasma as prepared by the "drying unit" is turned over to government agencies in the frozen state for proper storage and distributed according to their need. The bulk of it can remain as frozen plasma in large and permanent storage places strategically distributed through the country. A smaller portion is dried and turned over to the same agencies for storage or distribution to meet immediate requirements of isolated or remote units or areas not conveniently provided with frozen plasma. The store of frozen plasma is always available for use or drying as desired.

The proportion of frozen and dried plasma is to be determined by the requirements as they develop. It is reasonable to assume, however, that it is safe and convenient to store a large portion as frozen material.

By the plan just outlined the responsibility for the quality and safety of the material rests with a relatively small number of units, which must be well qualified for the work.

The suggested plan, on a national scale, would call for a coordinated effort on the part of the Army and Navy Medical Corps through the intermediary of such organizations as the National Research Council and its committees, the American Red Cross and its branches and the physicians and nurses of the various hospitals throughout the country acting as collecting and processing units. More specifically, the Army and Navy would state their need and lay down their requirements, the National Research Council would act to advise, organize and supervise concerning the technical details, and the Red Cross and its branches would attend to

the organization and calling of volunteer blood donors. This plan has been experimentally operating in Philadelphia and Bryn Mawr since September 1940. The apparatus used and the technic followed are described in detail separately.⁴ The results have been satisfactory so as to justify the suggested expansion of the plan outlined.

SUMMARY AND CONCLUSIONS

Considerations concerning the physiologic action of the various components of blood has led, of recent years, to the increasing use of citrated plasma as a substitute for whole blood transfusion. Clinical experience has fully confirmed the efficacy and safety of this material in a variety of conditions.

Technically, citrated blood plasma offers considerable advantages over whole blood, especially in the matter of preservation and ease of administration.

The choice of a method of preservation is a matter of primary importance. Storage in the liquid state is to be discouraged, because of the opportunity for bacterial growth and continuous deterioration of many essential elements as well as precipitation of fibrinogen.

The difficulties encountered in the storing of citrated blood plasma in the liquid state are completely eliminated by collection of blood, separation and pooling of plasma by a rapid closed method, followed by immediate freezing and preservation in the frozen state. This method of preservation is both simple and economical and provides optimal preservation for such labile elements as prothrombin, complement and fibrinogen. Preservation in the frozen state is the method of choice, adequate to supply the majority of needs of most hospitals.

Plasma preserved by freezing may at any time be dried from the frozen state. Dried plasma is of advantage in cases requiring concentration, such as cerebral edema, and in instances necessitating storage, transportation and administration under adverse conditions. It is estimated that, of all the plasma used, not more than 10 per cent needs to be dried.

Almost every hospital should be equipped to prepare and store plasma in the frozen state. It is not practical or necessary for the average hospital to dry plasma for its own needs. A few larger hospitals selected for their capability and with regard to the density of the population and means of transportation should be equipped to dry plasma from the frozen state, in quantity far exceeding their own needs. Thus they would be in a position to act as "drying units" for a large number of smaller institutions on a cooperative, non-profit basis.

These units would work at considerably less than full capacity. Thus not only would they be able to meet the ordinary requirements of civil life but they could be readily expanded to take care of local and national emergencies of civil and military nature. Under the conditions created by a national emergency, the securing of donors becomes a major problem, best handled by the American Red Cross. Bleeding of donors and processing of plasma should be done with the technical advice and under the supervision of a centralized authority, such as the National Research Council acting through its various committees. The bulk of plasma thus secured could be stored and distributed as frozen plasma. A certain portion of this could be dried by the units mentioned in anticipation to the expected needs.

PHYSICAL FITNESS

ERNST JOKL, M.D.

Consultant, Medical Aspects of Physical Education, South African
Defense Force; Head of Department of Physical Education,
Witwatersrand Technical College

AND

E. H. CLUVER, M.D.

Director, South African Institute for Medical Research
JOHANNESBURG, SOUTH AFRICA

Kessler¹ has drawn attention to the importance of attaining clarity with regard to the objectives of physical fitness. In fact, few basic medical terms are equally vaguely defined and similarly loosely used. Of the many aspects of fitness, we intend to deal in this paper with only one: that of physical efficiency. The fundamental importance of this problem has not yet been fully recognized by the medical profession. It is insufficiently realized that the standard of physical efficiency dictates largely the rate of industrial and agricultural production, that it is one of the primary determinants of military preparedness, that it has a bearing on the health of the nation and that it influences the rate of progress of education.

One of the main reasons for the difficulty of giving a clear definition of the term physical efficiency is lack of quantitative information on the subject. In his "Theory of Heat," one of the classics of modern physics, James Clark Maxwell² stated in 1871:

The most important step in the progress of every science is the measurements of quantities. Those whose curiosity is satisfied with observing what happens have occasionally done service by directing the attention of others to the phenomena they have seen; but it is to those who endeavor to find out how much there is of anything that we owe all the great advances in our knowledge. Thus, every science has some instrument of precision, which may be taken as a material type of that science which it has advanced, by enabling observers to express their results as measured quantities. In astronomy we have the divided circle, in chemistry the balance, in heat the thermometer, while the whole system of civilized life may be fitly symbolized by a foot rule, a set of weights and a clock.

"The 'instrument of precision' in the new science of labor is physical performance. The quantitative definition of a muscular action alone can be accepted as a measure of efficiency.

THE ECONOMIC ASPECT

In a recent study conducted in collaboration with Goedvolk and de Jongh we investigated the effect of a special training course on the health and economic situation of substandard recruits. Unemployment and unemployability, the latter question being closely related to that of the "poor whites," are serious problems in the Union of South Africa.³ Between 1935 and 1936, when this country experienced an unprecedented economic expansion, 118,939 persons were unemployed.⁴ These figures must be considered in the light of the fact that the entire European population in South Africa amounts to a little less than two million and that unemployment figures among the eight million Negroes in this country

have not been included. It is therefore obvious that the practical importance of the results obtained in our survey is considerable.

UNEMPLOYABILITY

The investigations to which we refer were conducted on a sample group of 32 young men who, during the 1935-1936 period of economic expansion, were unable to obtain or retain employment. According to the standards stipulated by labor and recruiting offices, as well as by the medical corps of the army, they were "fit." All of them had received primary education; they did not suffer from visible ailments such as manifest syphilis, flat feet or bad teeth, which according to the regulations, would have branded them "unfit." Nevertheless, most of them were unemployed or were working under conditions which were economically and otherwise unsatisfactory at a time when the labor market was flooded with demands for workers; for various reasons they seemed to be unemployable, or at least unable to find positions which suited them or for which they were suited.

What were the reasons for their plight? Tests of physical performance demonstrated that the power of endurance, the strength and the skill of these young men were low. As their poor educational qualifications rendered most of them unsuitable for anything except manual labor, their physical weakness represented a severe handicap. Some of the trainees had previously worked for short periods on farms but had lost their positions because of their insufficient capacity for physical labor. Their state of unfitness, which had not been "officially noticed" by the various authorities with whom they had been in contact, was also responsible for the mental dullness and for the lack of inner discipline which were found in an alarmingly large number of the recruits prior to their training course. The incidence of minor illnesses, such as colds, pain in the back, rheumatism, constipation, sore throats and headaches, was high. On account of their bad posture and lax general bearing, they made a bad impression on every employer.

All these factors combined to handicap these people in the economic field. Surely, they were "unfit," even if their official records did not state it. They were in a vicious circle. Their unfitness hampered their occupational career. They thus were kept on a subeconomic level of existence. Their poverty was responsible for an unsatisfactory diet, for bad housing and for poor general conditions of living. Their mental attitude became bitter. Few of them had sufficient initiative left to make an attempt at rescuing themselves from what in many cases appeared to be a hopeless situation.

SPECIAL TRAINING CAMP

A short time ago it was decided to establish a special battalion at military headquarters of the South African Defense Force at Roberts Heights "for the purpose of combating the deteriorating influence of unemployment,

Fig. 1.—Increase in body weight during a six months course (five measurements taken before and at six week intervals during the course). Means from thirty-two measurements.

The investigations to which reference has been made in this paper are being aided by a grant from the South African Research Council and Board, by the Secretary for Public Health, the South African Institute of Medical Research and the Witwatersrand Technical College.

and of providing discipline and training for unemployed boys and young men."

A strong effort was made by the departments of labor and defense, which collaborated in rural areas with the police authorities, to recruit young men of the type just described between the ages of 17 and 22. The minimum requirements were a primary school education and freedom from "disabling or infectious" disease. The young men underwent a six months course of training under military discipline, during which stress was laid on physical training and drill. Careful attention was paid to the diet, general living conditions and recreation of the recruits.

Fig. 2.—Drop of resting pulse rate during six months' training (five measurements taken before and at six week intervals during the course). Means from thirty-two measurements.

Our investigation was conducted with one of the first groups trained under this scheme. Physiologic, postural and anthropometric tests were undertaken before and at five stages during the six months course. The results of these studies were correlated with those of tests of athletic performance. This enabled us to assess critically the effect of the course on the working capacity of the trainees.

The results of the six months course on the recruits were truly remarkable. It is no exaggeration to say that the training transformed substandard youths, many of them of the poor white type, into normal young men. We can produce twofold proof for this statement: First, there is the medical evidence and, second, the economic result.

THE PHYSICAL EFFECTS

We can cite the results of our physiologic, anthropometric, postural and performance tests which demonstrate the rapid rise of different substandard conditions toward normal levels. Static phenomena such as posture, weight and resting pulse rate (figs. 1 and 2) as

Fig. 3.—Improvement of breath-holding time from substandard level during six months' training (five tests taken before and at six week intervals during the course). Means from thirty-two measurements.

well as functional reactions such as breath-holding time or the post-exercise decline of vital capacity, were studied at various stages of the training course, and the increase in organic efficiency could thus be quantitatively ascertained (figs. 3, 4 and 5). Working performances of the recruits, e. g. their 3 mile running times, showed a highly significant improvement (fig. 6). Their general attitude, physical as well as mental, changed during the training course (fig. 7). They no longer gave the impression of being "dull." They were dressed in well fitting uniforms which contributed to their looking "smart." They understood questions and had learned how to answer if spoken to.

THE ECONOMIC RESULT

Light was thrown on the practical importance of the physiologic effects of the training by an analysis of the economic position of the trainees before and after

the course. A labor bureau which was attached to the office of the commander of the training camp was able to provide for 90 per cent of the recruits who participated in the special training courses suitable employment at standard wages as paid to skilled European workers or apprentices in this country. During the period 1933 to 1939, 9,409 out of 10,735 "Special Service Battalion" recruits thus obtained employment. An analysis of the pay sheets for the first four years of employment of a sample group of these formerly dissatisfied, unemployed or unemployable workers revealed that the training, by rendering them physically fit, had really achieved their full economic rehabilitation. A widespread and serious social disease had been cured.

It is important to realize, at this stage, that it was primarily due to a new, unprejudiced and unorthodox definition of the term physical fitness that care could

be taken of this large group of persons. Many of them would have remained in a hopeless position if the current medical concept had been rigidly adhered to, according to which they had been labeled "fit."

THE PHYSIOLOGIC GROWTH OF PHYSICAL EFFICIENCY

During the last few years we have conducted a study of the growth of physical efficiency in children between 5 and 20 years of age. This investigation, which is based on more than twenty thousand individual tests, forms part of the malnutrition survey which one of us (Cluver) has organized on behalf of the government of the Union of South Africa. We decided to undertake this extensive survey because we were convinced that physical efficiency determines to

Fig. 4.—Response of vital capacity to a standard exercise (forty bendings of the knee in one minute) as tested before and during a six months training course.

a considerable extent the degree of "fitness" as it is understood under conditions of everyday life. The tests to which we refer here were conducted with English, Afrikaner, Jewish, Bantu, Cape Colored, Indian and Chinese children, who were subjected to three tests which had been selected with a view to ascertaining in exact terms the potentials of physiologic performance of the three basic constituents of labor—skill, strength and endurance. The children had to run 100 yards, put the 10 pound iron shot and cover the relatively long distance of 600 yards. Each performance was measured and recorded. The results were statistically analyzed.

RACIAL EQUALITY

We believe that this investigation has been the first of its kind, and some of the results obtained, therefore, have broken new ground. First of all we were impressed

with the similarity between the standards of physical performance found in the different racial groups. No more impressive evidence for the basic equality of man has ever been adduced (fig. 9). Second, we noticed that in our material biologic factors influenced the growth of physical efficiency more profoundly than environmental ones, although the potential interference of the latter must not be underrated.

We shall cite a few examples.

POWER OF ENDURANCE

The power of endurance of boys, as expressed in the progress in performance of the 600 yard running times, increases steadily within the age limits of our experimental material (fig. 10). The power of endurance of girls before puberty is about equivalent to that of the boys; it reaches an absolute maximum at the age of 13 years after which it declines. Thus Bantu girls of the group aged 18 to 20 are back on or below the level of performance of girls aged 6 to 7 years.

Fig. 5.—Continuous postexercise decline of vital capacity during training. The amount of postexercise decline of the state as well as of the rate of improvement of respiratory fitness. While before training the vital capacity of our recruits decreased after the standard exercise by about 750 cc., the corresponding figure after six months' training was 220 cc. (Five tests were taken before and at six week intervals during the course.) Means from thirty-two measurements.

labor, these physiologic features are expressed directly in terms of labor output and earning power of workers. On the sugar plantations of Natal (South Africa) unskilled Indian and Bantu agricultural laborers are being paid according to the number of yards of cane rows which they weed in a working day. In a sugar field of medium height, men finish about 1,000 yards a day. They receive a monthly wage of between 25s. 0d. and £2 10s. 0d. (\$9.06 and \$10.07). Women weed between 500 and 700 yards a day and receive between £1 0s. 0d. and £1 5s. 0d. (\$4.03 and \$5.03) a month. Children over 12 years of age, who weed 300 to 400 yards a day, receive 10s. (\$2.01) a month. Children under 12 years are not accepted.

Actually, the power of endurance of the latter group is far superior to that of the older ones: Among 1,877 children of different racial extraction in the group aged 4 to 6 years only 24 failed to complete the 600 yard running race in our tests. Out of 1,260 girls of the group aged 16 to 20 years 801 gave up or refused altogether to take part in the long distance running test. In sharp contrast to what is generally believed, our investigations have conclusively proved that working endurance as a basic physiologic phenomenon is greatest in young children (fig. 11).

We have recently demonstrated how, under primitive conditions of

In other words, the rates of growth of physiologic efficiency, of labor output and of earning power run parallel. This, to our knowledge, is the first example of a direct interdependence between physiologic and economic factors.

PUBERTY

Another important biologic event which exerts a profound influence on physical efficiency is puberty.

Although this influence is noticeable in boys as well as in girls, its effects are greatly different in the two sexes. In growing boys it retards the rate of progress in performance without interrupting it. In girls it practically brings the developmental progress of physical efficiency to a standstill; with regard to certain performances, e. g. those demanding endurance, it even initiates a decline. The only exception to this rule is that strength might still increase after puberty. As performances such as putting the shot, which we used as a test of strength, are largely a function of body weight, the postpuberal improvement in this direction can easily be explained. The girls gain weight and thus improve their performances. However, if one takes all the results of the different tests of performance into consideration, one can state that in girls puberty terminates the growth of physical efficiency⁵ (fig. 12).

Fig. 6.—Improvement of 3 mile running times during six months' training (five tests taken before and at six week intervals during the course). Means from thirty-two measurements.

Fig. 7.—Effect of a six months training course on height-weight correlations of 3 substandard recruits. The lines indicating minimum and standard levels in this chart and in figure 8 correspond with the requirements laid down by the United States Army Recruiting Office.

ADAPTATION ENERGY

We have based our interpretation of the effects of puberty on the growth of physical efficiency on the

5. We wish to emphasize that our tests have been conducted with children who had not previously undergone physical training. Thus we are dealing only with the problem of physiologic growth of physical efficiency. The question of the educability of children in standards of physical performance is not discussed in this paper.

important experimental work conducted during the last five years by Selye.⁶ This author has demonstrated that in addition to being able to effect specific physiologic adjustments the organism possesses a certain amount of "adaptation energy" which is mobilized in various emergencies. This reserve force may become exhausted if there is a simultaneous occurrence of more than one emergency. Selye's animals were able to overcome the effects of exhaustive physical exertion. They survived a specified period of exposure to extreme heat. They successfully fought against a well defined threshold dose of atropine. However, the animals died if they were compelled to perform the same amount of exhaustive exercise shortly after having recovered from poisoning with atropine. They died when they were exposed to the same hot environment from which they previously had escaped alive if the experiment was repeated with animals who had completed the exercise test.

In other words, we have to assume the existence of a nonspecific factor which enables a person to cope with emergencies provided such emergencies befall the person as single events. Should several emergencies arise at the same time, permanent damage or even death may be caused by the combination of factors each of which alone would have been harmless.

There can be no doubt that both puberty and physical activity represent physiologic "strains" which are capable of taxing the adaptation energy of the body to the utmost. The fact that we can demonstrate, during puberty, a physiologic tendency toward slowing down

unnecessarily strenuous activities such as rigid drill, as well as other physical efforts which lay undue stress on the reserve energy of the body, must be avoided.

NUTRITION AND PHYSICAL EFFICIENCY

In spite of its practical importance, little evidence has yet been presented with regard to the relationship

Fig. 8.—Effect of a six months training course on height-chest circumference correlations of 32 substandard recruits.

or even toward a temporary or final interruption of the growth of physical working power must be interpreted as an important biologic hint: During puberty,

Fig. 9.—The physiologic growth of strength, as expressed by the progress of performance in shot putting, was tested in English, Jewish, Cape Colored, Indian, Bantu and Chinese children between 6 and 16 years of age. There was an astounding similarity of the age performance standards as well as of the rates of growth of efficiency in the various racial groups. The Jewish boys were leading by a slight margin, probably because they mature a little earlier.

between nutrition and physical efficiency. During recent years numerous valuable clinical contributions to the subject have been made. But little is known about the effects on physical efficiency of physiologically deficient diets of the kind consumed by the working population all over the world. On previous occasions we have drawn attention to the paradoxical fact that it is the class of badly nourished people, of the white, black, brown and yellow carbohydrate eaters, who perform the bulk of manual labor on the six continents of the globe. While this observation certainly does not indicate that such a state of affairs should be regarded as satisfactory, this is surely a physiologic phenomenon of supreme interest.⁷

STANDARDS OF PERFORMANCE OF POOR CHILDREN

In the course of our investigations of the physiologic growth of physical efficiency, we have paid special attention to the question whether poverty, with its unfavorable effect in nutritional standards, causes a

Physiol.* 123: (Sept.) 1938.

7. Cluver, E. H., and Jokl, Ernst: A Survey of Physical Efficiency in South Africa, read before the 1940 annual meeting of the South African Association for the Advancement of Science, Johannesburg, July 1, 1940; *South African J. Sc.*, 1941.

deterioration in physical efficiency. We have compared the athletic performances of children of economically well situated parents with those of extremely poor ones. The tests on which the following statements are based were conducted on the pupils of the primary and secondary schools, respectively, in George (Cape Province). The pupils of the primary school came from extremely poor homes. Although none of them can be said to have suffered from caloric starvation, they lived mainly on a carbohydrate diet—maize, bread and potatoes were their daily fare—which was supplemented by little meat and scarcely any dairy products; however, a fair amount of fresh fruit and vegetables was available. The general conditions of living of this group were bad, and many of the children worked in their spare time on their parents' farm holdings. The children of the secondary school came from economically better situated homes; their general education and the standard of their environment were higher; their diet was better balanced, containing a satisfactory proportion of meat, dairy products and fresh fruit and vegetables.

In the prepuberal age groups we found no difference in physical efficiency between the two groups. After

who fixed a ski on his prosthesis and of a girl athlete whose left leg had been rendered 5 cm. short by the resection of a tuberculous hip joint. We have investigated numerous instances of professional boxers who

Fig. 11.—Effect of running 600 yards (endurance test) on girls of different ages. A study of the reactions of the children to the standard test has shown that the absolute running times are not the only criteria of their physical efficiency. After running 600 yards, girls of 6 years of age recover within two to five minutes; they sit at ease. Girls of 10 feel much more tired after the same performance; their breathing is strained; for a few minutes they are unable to talk; they support their trunks on their outstretched arms; the time of recovery is much longer than in the former group. Girls of 14 are uncomfortably tired after the 600 yards test; most of them lie down; their respiration is forced; pulse rates of 180 are not uncommon; within the ensuing hour girls of this group will not attend to ordinary work. After the same running performance, girls of 18 are exhausted; they frequently are in a condition approaching collapse; as a rule they flop to the ground and lie flat; their breathing is rapid and shallow; they cannot lift their heads; many of them will say that they actually have a feeling of suffocation; some vomit. If they try to stand up they may faint, i. e., vasomotor collapses. For hours, often even for the rest of the day, they feel weak, tired and incapable of doing any physical or scholastic work.

suffered from advanced cerebral disease caused by innumerable blows to the head, yet whose standard of physical fitness, as measured in terms of "fighting trim," was extraordinary high.⁸ We have recently observed

Fig. 10.—This graph is based on the results of tests of running 600 yards conducted with 482 Bantu girls and 571 Bantu boys between 6 and 20 years of age. The children were altogether untrained. The different developmental trends in the two sexes are obvious. In both groups there is an increase in endurance between 6 and 13 years of age. The endurance of the girls, as indicated by their running times, may even surpass that of the boys, as in this instance. From 13 years onward, however, a profoundly different development occurs in boys and girls. The girls show a rapid decrease of endurance, while the boys' running times continue to improve steadily. Thus girls of the group aged 17 to 20 years achieve the same running times as those 6 to 8 years old. Actually, young children are greatly superior in endurance to older ones.

puberty, however, there was a striking difference in the course of growth of physical efficiency between the "rich" and the "poor" children, the latter's standards of performance dropping below those of the former.

It thus appears that unless nutritional conditions are physiologically unbearable, e. g. if true clinical deficiency states are produced, the organism is capable of upholding, during the years of growth, a normal level of physical efficiency. Puberty, however, represents such a powerful additional strain that under the same dietary regimen normal standards or a normal rate of growth of physical efficiency can no longer be maintained. Either the quality of the diet is improved or working capacity decreases.

SOME CLINICAL ASPECTS

For a number of years we have published a large selection of case histories of athletes which demonstrate the fallacy of many generally accepted clinical concepts of the relationship between disease and physical efficiency.

We have described the case of a champion swimmer with dementia paralytica, of a first class ski-runner whose left leg had been amputated above the knee and

Fig. 12.—In women, the three components of physical efficiency in performance—strength, skill and endurance—grow at a steady rate from childhood to about the age of 12 years. At this stage, the onset of puberty causes a sudden interruption of this phase of development, and the prepuberal level of efficiency is maintained unchanged for about two years. After puberty, a characteristic differentiation of growth in performance occurs: Skill remains stationary. There is a gain in strength, explained by the increase in body weight and muscular development. Endurance, however, declines. Girls of the group aged 16 to 20 years have an endurance equal or even inferior to that of children of the 5 to 9 year class.

a gymnastic instructress with myasthenia gravis who, when taking a prostigmine preparation, could continue her professional activity; a shot-put champion with a

8. Jokl, Ernst: The Medical Aspect of Boxing, Pretoria Union of South Africa, J. L. Van Schaik, 1941.

congenital defect of the major pectoral muscle on the right side⁹ (fig. 13), an excellent runner with advanced syphilitic osteopathy of both tibias (fig. 14) and a girl aged 18 years with paralytic and paretic remnants of poliomyelitis affecting the right thigh, lower leg and foot, who ranked among the leading long distance swimmers in her town.

We have paid special attention to the hitherto much neglected problem of the effects of cardiovascular disease on physical efficiency. We have reported the case of a marathon runner with aortic regurgitation and mitral stenosis.¹⁰ We have studied in detail the 25 athletes with aortic regurgitation. An analysis of the occurrences of fatal collapse during exertion revealed that circulatory disease, even if so severe that it acutely threatens life, often does not at all impair physical efficiency. In fact, we have encountered several examples of famous sportsmen dying from long-existing circulatory illness during or shortly after having successfully taken part in competitive athletic events.¹¹

Among the 67 deaths during or after exertion on which our analysis was based was that of a first league football player who died after a game; autopsy revealed advanced lipoidosis of the intima of the aorta, of the aortic valves and, most severe, of the coronary arteries. A tennis champion died after a match from rupture of the aorta. Two runners dropped dead on the track in whom necropsy revealed, respectively, rupture of an aneurysm into a tuberculous pulmonary cavity, and aortic stenosis, chronic endocarditis and an organized thrombus in the right branch of the coronary artery. A competitor in a long distance race died from mesoarteritis syphilitica: The superior portion of the ascending aorta was dilated and the intima roughened; there were numerous whitish scars in the thickened aortic wall, yellow spots covered the media, the coronary ostia were greatly narrowed and the coronary lumens were much decreased.

A few months ago we analyzed 2 cases in which death occurred during exertion, both of apparently healthy

myocardium, in which muscle fibers were replaced in many spots by fibrous tissue, and an extraordinarily narrow coronary artery (figs. 15 and 16). The other was a Rugby player who died after a test game. He had a cystically degenerated right kidney the size of a walnut, a greatly hypertrophied left kidney, a much

Fig. 14.—Legs of Indian child with osteopathy of syphilitic origin. This patient was discovered in the course of athletic tests conducted with school children. The child, who had no complaints whatever, is an excellent runner.

enlarged heart with a degenerated myocardium and thick, prominent, atheromatous patches in the coronary arteries and a hypoplastic abdominal aorta. There was a persistent thymus, in which microscopic examination revealed much active tissue. On account of his outstanding feats on the playing field the deceased had been called "the iron man of South African Rugby football."¹²

We do not look on experiences of this kind primarily as curiosities. Such observations teach us rather that many of our present concepts of physical efficiency and fitness need to be revised, that the limits of plastic adaptation of the human organism are much wider than is generally believed, that physical training, as clearly distinguished from "remedial work," must be elevated to a fully recognized branch of medical therapeutics in order to achieve the desirable results but that it is necessary to state for each condition and for each case whether it is medically possible to tax the person's potential of adjustment to the utmost.

One of us (Jokl) has recently been asked by the Defense Department to place experiences of the kind described at the disposal of a special battalion which treats, as well as trains and develops to the limit of their efficiency, recruits who for medical reasons do not satisfy the demands stipulated by the Army Recruiting Office. Highly trained physical training instructors and physical therapists are attached to this battalion, and closest collaboration is maintained with the various clinical branches of the Army Medical Corps. Most

of those who were formerly rejected are now reclaimed and conditioned by a combined medical and physical educational effort; we thus transform second rate raw material into the finished product of trained soldiers and workers.

CONCLUSIONS

In the future if we speak of fitness and efficiency we shall have to ask ourselves Fitness and efficiency for what? A man may be fit as a paper hanger without being fit to decide the destiny of a continent. Lange¹³ has described the history of a habitual criminal who became a celebrated hero under conditions of war. Some people are efficient piano players but are unfit to work as miners. Others are physically capable to do clerical work in a city but would be "lost" on a farm. A man without legs is unfit for walking but may be an outstanding fighter pilot.

Problems of this kind have their medical aspect as well as their economic, educational and social aspects.

Theories on and concepts of physical efficiency will automatically change when more physiologic and clinical experiences in this field are presented in the medical literature. This, however, will be possible only if the amount of research conducted on this subject is in accordance with its practical importance.

Finally, we wish to express the belief that a closer study of the medical aspect of physical efficiency will introduce a new dynamic concept into clinical medicine.

the extent to which functional adjustments are possible in the healthy as well as in the diseased human organism; it will thus take medicine further away from an era in which anatomic changes are regarded as the sole criteria for the interpretation of physiologic and pathologic conditions.

Fig. 16.—Extent of the infiltration of fibrous tissue in the heart muscle shown in figure 15 (stained with van Gieson stain and hematoxylin). The condition of the heart muscle was responsible for the fatal collapse of the young woman. It did not, however, prevent her from exercising and indulging in strenuous physical activities right up to the time of her death.

Fig. 15.—Heart of 16 year old girl who died during a ball after having danced for four hours: A, open ductus arteriosus; B, subaortic stenosis; C, greatly hypertrophied myocardium.

Such a study will develop a strong sense of reality by placing the medical implications of economic, social and educational problems in their correct perspective. It will facilitate new applications of physiologic information to hitherto neglected clinical issues. It will show

SUMMARY

1. Closer study of medical problems of physical fitness is to be encouraged.
2. Experimental results have thrown light on the relationship between physical fitness and employability.
3. The physical improvement of substandard recruits obtained in a six months training course and the economic implications of such improvement are noteworthy.
4. An interracial survey of the physiologic growth of physical efficiency, conducted with English, Afrikaner, Jewish, Bantu, Cape Colored, Indian and Chinese children, revealed a striking similarity between the standards of physiologic performance of the different racial groups.
5. The effect of puberty on the growth of physical efficiency is noteworthy. It is desirable to collect more evidence on the relationship between subclinical nutritional deficiencies and physical efficiency.
6. Clinical evidence demonstrates the fallaciousness of many accepted clinical concepts of the relationship between disease and physical efficiency.

The Father of the Empirical Scientific Method.—Francis Bacon (1561-1626), the Lord Chancellor of England in the reign of Queen Elizabeth, is known as the father of the empirical scientific method. For the first time he logically formulated the inductive law of scientific discovery. This law sought to discourage the custom of seeking theological or metaphysical explanations for natural phenomena and to encourage the limitation of science to the facts of experience. He advocated replacing faith and belief with doubt and inquiry, and urged the student to utilize his senses and reasoning powers in observation and experiment and thus to acquire a knowledge of the universe. His rules for scientific observation and experiments are well known to all scientists, and in this way he exerted an influence on psychiatric thought as well as on all medicine.—Lewis, Nolan D. C.: *A Short History of Psychiatric Achievement*, New York, W. W. Norton & Co., Inc., 1941.

OSTEOMYELITIS OF THE FEMORAL
NECK AND HEADCAUSED BY BACTERIUM NECROPHORUM
(BACILLUS FUNDULIFORMIS)FREMONT A. CHANDLER, M.D.
AND

VIRGINIA M. BREAKS, A.B.

CHICAGO

The group of nonsporulating anaerobes described in the literature under the names *Bacterium necrophorum*, *Bacillus funduliformis* and a number of others has been found in various pathologic conditions in man and animals. These conditions include septicemia, abscesses of the liver, lungs and subcutaneous tissues and inflammations of the joints. In a comparative study by Dack, Dragstedt and McCullough¹ the strains from diseases in man, represented by *B. funduliformis*, have been shown to present no clearcut differences from the strains reported usually in animal and occasionally in human disease and represented by *Bact. necrophorum*. Dack

Fig. 1.—Appearance, Oct. 15, 1937, five days after admission. Thinning of joint space is evident.

and his associates,² describing these organisms in their studies of ulcerative colitis, placed them in the genus *Bacterium*, since they lack a characteristic of the genus *Bacillus*, the ability to form spores. These workers retained the name *Bact. necrophorum* on the basis of priority.

The literature on these nonsporulating anaerobes has been reviewed in a book by Weinberg and his associates³ and in an article by Brunner.⁴ Numerous additional reports, the majority of them reports of septicemias, have appeared since these reviews were written. Two of these articles⁵ dealt particularly with

the surgical aspects of infections due to these anaerobes. It is significant that pyarthrosis was mentioned as occurring frequently. Our search of the literature failed to reveal any case of osteomyelitis due to *B. funduliformis* or *Bact. necrophorum*. One fatal instance of osteomyelitis due to a closely related strain, *Bacterium halosepticum*, was described by Wyss⁶ in 1904.

REPORT OF A CASE

W. H., a white boy aged 12 years, was admitted to the hospital Sept. 30, 1937 with draining of the left ear of two weeks' duration and pain in the right hip of three days' duration. The patient had suffered from chills on two occasions, and his temperature had shown a daily elevation to 104 F. for seven days. His temperature on admission was 104 F. The past history revealed no diseases except scarlet fever.

Physical examination revealed that the boy was well developed, semistuporous and acutely ill. General examination showed no disorders except tenderness of the left mastoid region and drainage from the left external ear. The right thigh was held in 100 degrees flexion and 70 degrees abduction. Definite fullness was present about the anterior and posterior aspects of the area of the hip and severe muscular spasm about the hip in all directions. The temperature was 104 to 106 F. The hemoglobin content was 75 per cent, red blood cells numbered 4,300,000 and white blood cells 14,200, with polymorphonuclear leukocytes 80 per cent and lymphocytes 20 per cent. A cutaneous tuberculin test gave negative results. Reaction to the Schick test was positive. Wassermann and Kahn reactions were negative. Treatment with fluids given by rectum, dextrose given intravenously and apple juice and water given by mouth was initiated on admission. A blood culture was taken.

October 2 a lumbar puncture was made. The spinal fluid showed 243 cells, of which polymorphonuclear cells made up 92 per cent. The Pandy test showed globulin 1 plus. The right hip was aspirated anteriorly and a small amount of pus obtained. A posterior incision was made and about ½ ounce (15 cc.) of thin, yellow-green, foul-smelling pus was obtained. A rubber tube drain was sutured to the capsule with a petrolatum pack to the wound. Traction was applied to the right leg (fig. 1). Sixty cc. of blood was given intravenously on October 2 and 150 cc. on October 4. A mastoidectomy was performed on the left side. Much pus was found over the lateral sinus and dura. Smears and cultures were made. On October 4 paralysis of the sixth and seventh cranial nerves on the left side was noted.

October 8 the hemoglobin content was 50 per cent, red blood cells 2,300,000 and white blood cells 18,500. The differential count showed polymorphonuclears 85 per cent and lymphocytes 15 per cent. Examination of the urine gave negative results. Drainage from the left mastoid region and the right hip continued. The temperature was 99.2 to 103.2 F.

October 14 an abscess over the medial posterior aspect of the right thigh was incised and about 15 cc. of thin, greenish, foul-smelling pus obtained. Drainage continued from the left mastoid.

October 17 the right leg was found to have assumed a position of external rotation, and a clinical diagnosis of slipping of the capital epiphysis was made. A double spica cast was applied after internal rotation of the right leg (fig. 2).

The patient's serum on October 13, October 18 and November 6 did not agglutinate *Brucella abortus*, *Brucella melitensis* or *Brucella tularensis*. A blood culture was made October 18 in liver infusion broth and in Rosenow's medium.

Transfusions were given on October 21 and October 26.

November 14 involvement of bone at the upper end of the femur was extensive, with evident sequestration of the neck and trochanteric areas (fig. 3). The patient continued to have a septic temperature, and his general condition remained unchanged. He occasionally complained of pain in the anterior aspect of the right hip. Moderate amounts of pus drained from the wounds. On November 12 the external ear was dry, and on November 30 the mastoid wound was dry and practically closed.

6. Wyss, O.: *Ueber einen neuen anaeroben pathogenen Bacillus. Beitrag zur Aetiologie der akuten Osteomyelitis*, Mitt. a. d. Grenzgeb. d. Med. u. Chir. **13**: 199, 1904.

Through December the patient continued to have a septic temperature, which gradually subsided. The old sinus just below the wound on the right hip began to discharge profusely. An abscess developed in the right inguinal region. On Jan. 31, 1938 the inguinal abscess was aspirated and about 1 cc. of

Fig. 2.—Reduction of slipped femoral epiphysis, October 18.

purulent material obtained. This abscess and the sinus of the hip continued to drain.

March 22, because of increasing formation of sinuses, sequestrectomy of the head, neck and trochanteric areas of the right femur was performed (fig. 4). After the operation the condition of the patient improved steadily. Through April the wound continued to drain moderately. May 17 granulation tissue had formed, and there was slight drainage still present around the area of granulation.

July 7 the patient was walking on a caliper brace. There was no drainage. The patient's recovery continued uneventfully through August, and he was discharged from the hospital Sept. 8, 1938.

June 13, 1939, although protected by a walking caliper brace, the femur subluxated from its position in the acetabulum. A

Fig. 3.—Roentgen sequestration of femoral trochanters, neck and head, Jan. 24, 1938.

well-leg traction cast was applied. A massive graft taken from the anterior aspect of the femur was placed to engage in the acetabulum to preserve the length of the leg. This graft survived, giving stability to the hip.

May 8, 1940 the gait was stable, but increasing adduction of the femur was present. Shortening, to the extent of 1½ inches

(3.8 cm.), had occurred. Osteotomy was proposed. The patient's general health was excellent.

BACTERIOLOGY

Smears made from the specimens of pus aspirated from the hip joint and from the perisinal abscess on Oct. 2, 1937 revealed many small pleomorphic gram-negative organisms, varying in size from coccobacilli to bacilli slightly longer than colon bacilli. The predominating form was that of a short slender rod. The organisms stained poorly and showed some bipolar and granular forms. The aerobic cultures remained sterile. In one tube of Rosenow's medium there was a slight growth of slender gram-negative rods over the pieces of brain at the bottom of the tube where anaerobic conditions exist. No other anaerobic cultures were made from the pus. The rods from the Rosenow broth failed to grow in either aerobic or anaerobic subcultures.

Direct smears from the infected ear made at about the same time as the aforementioned smears showed a few gram-negative rods mixed with gram-positive cocci in groups. Aerobic cultures only were made, and the bacilli did not grow.

A portion of the sequestrum from the head of the femur removed on March 22, 1938 was ground with sterile broth, and smears and cultures

were made. In direct smears, a few organisms were found resembling those in smears from the pus. No growth occurred in aerobic cultures. From anaerobic cultures in 0.1 per cent cystine blood agar slants and from Rosenow's medium, gram-negative organisms were isolated which appeared identical in form with those described in literature as *B. funduliformis* and *Bact. necrophorum*. A striking pleomorphism was exhibited by the organisms, particularly on blood agar and cystine blood agar. In one twenty-four hour culture there were forms resembling those described by Dack, Dragstedt and McCullough¹ on ascorbic acid medium. These

forms were irregular staining and filamentous, with bulbous swellings which gave them a bizarre appearance. Usually, however, the form was that of one or more of the three characteristic types described in the literature: small bacilli, filaments and spherical forms (fig. 6). Filamentous forms, sometimes looped about to form tangled masses, were usually predominant in young cultures. The spherical forms, varying in size and in intensity of staining and showing numerous ghost forms were found in older cultures. Neither spores nor branches were formed.

These organisms were strict anaerobes and died in a short time on solid mediums when exposed to the air. In culture in deep brain medium they remained viable after several weeks at room temperature. The organisms were fastidious in their requirements for growth, the addition of such substances as blood, brain tissue or cystine being necessary. In all of the cultures a butyric acid-like odor developed. Colonies on blood agar were small, round, elevated, grayish and about 0.15 to 1 mm. in diameter. As in the cultures described by Dack and his associates,¹ hemolysis of the alpha type appeared around the colonies only after they had been exposed to atmospheric oxygen. After longer exposure the zone would often com-

Fig. 4.—Roentgen appearance June 1, after sequestrectomy.

pletely clear. In Rosenow's medium growth occurred only over the pieces of brain at the bottom of the tube. Gas was produced in this medium. Motility was not observed in twenty-four or forty-eight hour broth cultures.

The biochemical characteristics of the organism were tested in a basic medium of 0.1 per cent cystine veal infusion broth. Indole was produced when dextrose and tryptophan were added

Fig. 5.—Roentgen appearance April 8, 1940, showing graft of bone in place.

to the basic medium. Hydrogen sulfide was formed. Gelatin was not liquefied. Fermentation reactions were tested in a soft agar basic medium to which carbohydrates were added in 1 per cent strength, bromocresol purple being used as an indicator. Acid and gas were produced in dextrose and levulose. Sucrose, lactose, maltose, salicin, inulin and mannite were not fermented after two weeks' incubation. No growth occurred in cystine litmus milk.

A number of blood cultures made in Rosenow's medium remained sterile.

ANIMAL INOCULATIONS

Guinea pigs and rabbits were inoculated to test the pathogenicity of this strain for laboratory animals. Two guinea pigs were inoculated intraperitoneally, 1 with 1 cc. of

Fig. 6.—Section of stained smear of forty-eight hour culture on cystine blood agar slant, showing bacilli and a few filaments.

the ground emulsion of the bone removed from the patient, the other with 1 cc. of a brain broth culture of the organisms. Both remained healthy. Four rabbits were inoculated with cultures of the organisms. In 1 given an injection sub-

cutaneously a small firm nodule developed six days later at the site of inoculation. Four days later this nodule had disappeared, and the rabbit showed no further evidence of infection. One rabbit inoculated intravenously showed no evidence of infection. In an attempt to produce osteomyelitis, the inoculations were made directly into the shafts of the femurs of 2 rabbits. One of these animals showed no signs of infection. In the other a firm mass about 4 mm. in diameter appeared in the subcutaneous tissue of the wall of the lower part of the abdomen about ten days after inoculation. Five weeks after inoculation the rabbit was weak and emaciated and seemed to have lost the use of the inoculated leg. Cultures of the heart blood were made in the deep brain medium. The rabbit was then killed and an autopsy performed. The subcutaneous abscess was encapsulated. It was filled with thick white stringy material having a foul odor. A similar though smaller abscess was present in the soft tissue near the head of the right femur. The joints showed no inflammation, and no gross changes were visible in the bone. The liver, spleen and kidneys appeared normal. The blood culture remained sterile. Gram-negative rods were found in large numbers in smears of the pus from both abscesses. *Bact. necrophorum* was recovered from both in pure cultures.

The invasive ability of this strain was shown in the production of the lesion about 9 mm. from the original injection in the shaft of the femur. That this lesion was well localized is interesting, in view of the localized lesions produced by this strain in the patient.

After this animal passage, cultures of the organisms were injected in 2 rabbits, in 1 intravenously and in 1 subcutaneously. Death of both occurred within seventy-two hours. This was probably due to the fact that the growth of the organism was much enhanced by animal passage, as the virulence of a strain usually remains unchanged and produces the same type of lesion repeatedly.

COMMENT

The ability of *Bact. necrophorum* in pure culture to invade tissue and to become localized is strikingly demonstrated in the case described.⁴ Brunner stated that in children the focus for a general infection with this group of anaerobes is almost without exception otitis media with mastoiditis. It seems probable in this case that the middle ear was the primary focus, especially since gram-negative bacilli which did not grow out in aerobic cultures were seen in direct smears.

As has been stated by Dack and his associates,⁷ by Brunner⁴ and by others, infections due to these bacilli are probably much more common than is ordinarily supposed. Shaw's⁸ suggestion that nontuberculous abscess of the psoas muscles may often be due to these anaerobes has been substantiated in a recent case reported by Ortmayer.⁹

The increasing number of infections due to *Bact. necrophorum* reported in the literature and their seriousness or fatal outcome makes their recognition worthy of more consideration.

CONCLUSION

In a case of osteomyelitis of the femoral head and neck of obscure causation extensive studies proved the process to be due to *Bact. necrophorum*. Although this is apparently the first case of its kind reported in the literature, it is probable that this disease process would be found more often if similar studies were made.

Suggestions and confirmation of the bacteriologic study were made by Dr. Gail M. Dack.

Clinical Notes, Suggestions and New Instruments

RAT-BITE FEVER IN AN INFANT BITTEN AT THE AGE OF ELEVEN DAYS

JOSEPH GREENGARD, M.D., AND EDMOND R. HESS, M.D.
CHICAGO

A careful search of the literature has failed to reveal a case of rat-bite fever in an infant as young as the one observed by us. For this reason it is felt desirable to record this instance of an infant who was bitten by a rat at the age of 11 days and in whom the incubation period and course of the disease could be observed in detail. The youngest child previously reported, an infant aged 3 months, was described by Sanders¹ in 1922. Bayne-Jones² collected 75 cases occurring in the United States from 1839 to 1930. Only 9 of the patients were under 2 years of age.

REPORT OF CASE

History.—C. B., an infant Negress aged 11 days, entered the hospital on April 19, 1940 about two hours after having been bitten by a rat while sleeping in her crib. Physical examination showed nothing abnormal except for the left hand, which appeared swollen and revealed several deep tooth marks on the thenar eminence which were oozing blood. The wound was cleansed with green soap and a dry dressing applied. Antirabies vaccine was administered in doses of 1 cc. daily for twenty-one days.

The wound healed quickly and the hand resumed a perfectly normal appearance until May 1 (twelve days after the bite), when a deep-seated induration was first noted in the left thenar eminence. In the next few days the thumb became swollen, and a small hard red area appeared at its base. On May 4 (fifteen days after the bite) the axillary temperature rose to 101.2 F. The following day it was normal, but on May 6 it rose to 102 F. On May 7 induration and redness of the left thenar eminence and the first phalanx of the index finger at the site of the tooth perforations had increased. Although no lymphangitis was noticed there was a definitely palpable epitrochlear gland about the size of a buckshot and an axillary gland the size of a large pea on the left. Axillary temperature ranging between 101 and 103 F. continued for the next five days. A blotchy, erythematous eruption appeared on the trunk at the onset of the febrile stage and persisted for several days. The general condition of the infant remained excellent. A diagnosis of rat-bite fever was made.

An afebrile period of one week then ensued, but on May 19 the axillary temperature again rose to 100.2 F. and the red blotchy cutaneous eruption reappeared. By this time the local lesion on the thenar eminence and on the index finger had resolved to a considerable degree, but the abnormality in the axillary and epitrochlear glands persisted.

After an afebrile period of four days the temperature rose to 103.4 F., and a purulent nasal discharge was noted. The ear drums were reddened, but the landmarks were distinct. The chest was clear. The rash had disappeared completely. Obviously an intercurrent infection of the upper part of the respiratory tract had occurred. The following day the temperature rose to 104.8 F. Sulfapyridine was initiated by mouth in doses of 1¼ grains (0.7 Gm.) a day. Both ear drums were definitely bulging, and a bilateral paracentesis was done with drainage of thick pus.

The infant continued to have a septic axillary temperature of 101 to 103 F. An ulcerative lesion appeared in the gum occupying the position of the upper right lateral incisor tooth bud. There appeared to be a small fistulous track with a dirty grayish material covering it. The right cheek seemed slightly fuller than the left. A smear taken from the necrotic area was negative for spirochetes, and a roentgenogram of the maxilla was negative.

From the Children's Division of the Cook County Hospital and the Loyola University School of Medicine.

2. Bayne-Jones, Stanhope: Rat-Bite Fever in the United States, Internat. Clin. 3: 235 (Sept.) 1931.

In the next few days the fever subsided. On June 2, however, the axillary temperature suddenly rose to 106.6. Respirations became grunting and the abdomen distended. On physical examination dullness was obtained over the entire right portion of the chest, a few coarse rales were heard and the ears were draining pus profusely. June 3 the infant died, one month after the onset of rat-bite fever and two weeks after the onset of the intercurrent infection of the respiratory tract.

Laboratory Examinations.—The organism was isolated by inoculation in mice during the first febrile episode. On May 14 several white mice whose blood was found negative for spirochetes by dark field examination were inoculated intraperitoneally with whole blood obtained from the infant. Thirteen days later stained smears of the peripheral blood from one of the inoculated mice were examined and the typical organism of rat-bite fever (*Spirochaeta morsus muris*) was found. Subsequent blood smears from the other mice also revealed the spiral organisms.

Urinalysis consistently showed the urine to be normal except for the admission urine, which showed albumin and an occasional finely granular cast.

The blood showed gradually progressive anemia. The hemoglobin dropped from 15.6 Gm. to 11.0 Gm.; the erythrocyte count fell to 3,680,000; the leukocyte count was 14,700 with 59 per cent neutrophils, 34 per cent lymphocytes and 7 per cent monocytes.

The blood Wassermann and Kahn reactions were persistently negative until two days before death, when the Kahn reaction became positive (3 plus). Blood cultures were consistently negative for spirochetes.

Roentgenograms of the chest and long bones were normal. Mantoux tests with 0.01 mg. and 0.1 mg. old tuberculin gave negative results.

Autopsy.—Dr. J. J. Kearns, coroner's pathologist, performed an autopsy which revealed the following abnormalities: The lungs were subcrepitant and studded with pinpoint to split pea-sized hemorrhagic areas. On cut surfaces the upper lobes were pinkish red and granular. The mucosa of the trachea and bronchi was swollen and dusky red. The tracheobronchial lymph nodes were enlarged. The pericardial sac contained about 20 cc. of amber-colored fluid with flecks of fibrin. The myocardium was pale and soft; the endocardium revealed no changes. The intima of the aorta and coronary arteries was discolored lemon yellow.

The peritoneal surfaces were smooth, dry and dull. The liver weighed 195 Gm. and was dark brownish red and firm. The gallbladder was enlarged to 6 by 3 cm.; the wall was pale lemon yellow. The spleen weighed 55 Gm., and its capsule was covered with loosely adherent gray-yellow membrane in places. The splenic pulp was semifirm and dark brownish red, and the markings were indistinct. The kidneys together weighed 40 Gm. and were pale and studded with punctate and echymotic hemorrhages. The mucosa of the esophagus, stomach and small bowel was swollen and dark gray. The head was not opened.

Microscopic sections were made of the various tissues, but a thorough search by special staining technic failed to reveal the spirochetes.

The anatomic diagnosis was (1) bilateral hemorrhagic bronchopneumonia, (2) acute serosanguineous tracheobronchitis, (3) serofibrinous pericarditis, (4) cloudy swelling of the myocardium, liver and kidneys, (5) hemorrhagic nephritis, (6) septic hyperplasia of the spleen and (7) hydrops of the gallbladder.

COMMENT

Rat-bite fever has a worldwide distribution, and many cases have been recorded in the literature. Transmission of the disease occurs through the bite of an animal, most commonly the rat, though other animal vectors have been responsible, notably the cat, weasel, dog and pig. Opportunity for such infection is not common in early infancy, and a rat bite sustained at the age of 11 days is remarkable. That such an incident can occur in a modern American urban community is of great sociologic significance. Infestation with rats is widespread in Chicago, and at Cook County Hospital a relatively large number of rat bites are observed in young children. The community has made little effort to correct this situation.

The onset of the first bout of fever occurred in the infant under observation exactly fifteen days after the bite. Four days prior to this, twelve days after the bite, the local lesion at the site of the tooth perforations on the hand made its first appearance with the evolution of a deep-seated induration associated with edema of the thumb and index finger and a lymphadenitis involving the epitrochlear and axillary glands. With the onset of the fever a generalized macular erythematous lesion appeared, lasting several days. After an afebrile interval a second bout of fever and erythema occurred, and then, unfortunately, an intercurrent infection of the respiratory tract supervened which terminated in hemorrhagic bronchopneumonia and death.

When the first febrile episode occurred an effort was at once made to isolate the specific etiologic factor by animal inoculation, since direct examination of the infant's blood failed to reveal the spirochete. This procedure was successful, and the organism was demonstrated in stained smears of the peripheral blood of the mice inoculated. The organism is a spiral called *Spirochaeta morsus muris* and was first described by Futaki and his associates.³ It is a short spiral from 2 to 5 microns long with about four curves. The Wassermann reaction may be positive in cases of rat-bite fever but is not consistently so. A positive Kahn reaction was obtained in this child before death, which was due to an intercurrent sepsis. In uncomplicated cases the prognosis is usually good. Therapy is by the use of arsenicals.

SUMMARY AND CONCLUSIONS

1. An infant Negress aged 11 days was bitten by a rat, and rat-bite fever developed.
 2. The incubation period in the infant described was twelve days.
 3. The specific organism was isolated by animal inoculation.
 4. Two typical episodes of fever and erythema occurred with a characteristic local lesion.
 5. Death resulted from an intercurrent infection with hemorrhagic bronchopneumonia.

A TEST TUBE GUARD

J. ROBERTSON KNOWLES, M.D., BOSTON
Surgeon, Boston and Maine Railroad

Any one who has occasion to examine urines, and especially a person who heats Benedict solution over a Bunsen burner or an alcohol lamp, knows how easy it is to have the solution boil up and, with considerable force, go all over the wall or surrounding objects.

For that reason I have devised a guard for a test tube which is simple, can be easily made, is inexpensive and gives perfect protection.

The guard, as may be seen in the accompanying illustration, is made of an ordinary large light teaspoon, by means of a pair of tin clippers. The handle is cut off from the spoon, which leaves the bowl of the spoon together with $1\frac{1}{2}$ inches of the stem. The bowl of the spoon is then bent down, with the concave surface facing downward. The stem of the spoon is then soldered to a tin spring, which can be procured at any tinsmith's shop, and cut and bent to fit the diameter of the test tube. This spring does not allow the guard to slip, and it allows the examiner to snap the guard off and on to the test tube with the greatest of ease.

Test tube guard.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

THE FUNCTION OF THE ADRENAL CORTEX

EDWARD C. KENDALL, PH.D.
ROCHESTER, MINN.

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—ED.

When the adrenal glands are removed from laboratory animals, symptoms of deficiency develop, which may be summarized as follows: The first notable change is usually a loss of appetite, which is soon followed by nausea, vomiting, increased peristalsis and eventually bloody diarrhea. Associated with these changes are profound weakness of the muscles and a listless stupor, or, in some animals, restlessness and marked salivation, with clonic movements and general convulsions similar to those observed in hypoglycemia induced by insulin. There is a gradual decrease in body temperature and a decrease in the basal metabolic rate.

Continuance of the state of adrenal deficiency is invariably associated with a decrease in blood pressure to the death level, an increase in the hematocrit reading and a progressive decrease in the volume of the circulating blood. Soon after removal of the adrenal glands there is a marked and continuous increase in the concentrations of nonprotein nitrogen and potassium and a decrease in the concentrations of sodium and chloride in the blood serum.

The concentration of dextrose in the blood and of glycogen in the liver depends on whether the animal ingests food. With a daily intake of food the blood sugar may be within normal limits, but if an adrenalectomized animal does not eat, the blood sugar level drops rapidly and glycogen disappears from the liver.

The administration of an extract from the adrenal cortex promptly reverses the trend of the changes outlined. After a short interval the profound weakness and prostration are relieved, and within a few hours the concentrations of sodium and chloride increase. The potassium and nonprotein nitrogen in the serum decrease more slowly to normal. If the deficiency has been allowed to progress nearly to the point of death, treatment with an extract from the adrenal cortex for several days may be required before the appetite returns to normal and the animal can be considered fully restored.

One of the most interesting and important observations is that of the influence of sodium and potassium salts. The administration of potassium salts rapidly aggravates the condition and may cause the death of the adrenalectomized animal. The administration of a diet high in sodium chloride and sodium citrate or sodium bicarbonate with a low content of potassium has such a beneficial influence that the amount of

extract of adrenal cortex required may be greatly reduced, and eventually the animal may be maintained in a normal condition without the administration of any cortical substance.

Although the concentrations of the constituents of the blood in such an animal may be within normal limits, and although the appetite, weight and body temperature and the general condition may be normal, the animal cannot withstand stress and may rapidly succumb to a high intake of potassium salts, a low environmental temperature, violent exercise or, in particular, a sudden withdrawal of sodium salts from the diet.

After the successful preparation of an extract of adrenal cortex which would maintain the life of adrenalectomized animals, investigators immediately became interested in a study of its mode of action. A wide divergence of opinion soon became evident. The regulation of carbohydrate metabolism as the prepotent action of the adrenal was suggested and vigorously upheld. Changes in blood pressure and in the volume of the blood and the distribution of electrolytes and water seemed of primary importance to another group. A possible relation between the adrenal cortex and mineral metabolism, including renal function and the excretion of sodium and potassium, was investigated by still others.

Early in the investigation Hartman and his associates¹ suggested the name "cortin" for the hormone of the adrenal cortex, and until quite recently all physiologic effects produced by an extract of the adrenal cortex were ascribed to the vital principle of the gland. In 1934 crystalline compounds were separated, and by 1938 several crystalline compounds, shown in the structural formulas, had been isolated, some of which showed marked physiologic activity. These compounds were designated as cortin-like, which indicated physiologic activity of the same quality but quantitatively inferior. The chemical investigation of the gland has now been carried to the point where the active extract can be separated into fractions either as crystalline compounds or as purified amorphous material, and the physiologic investigation of this series of individual compounds has raised an important question. Does the adrenal cortex elaborate one compound which can be regarded as the vital hormone of the gland, or does it prepare a number of hormones, each with a special and specific function? The results presented in this paper answer this question and indicate that no one compound can be regarded as the vital or essential hormone which can produce all the physiologic effects of the gland. Some of the physiologic activities which are influenced by the adrenal cortex are indicated in the following outline:

PHYSIOLOGIC ACTIVITIES AFFECTED BY THE ADRENAL CORTEX

The physiologic activities affected by the adrenal cortex are carbohydrate metabolism, capacity of muscle to respond to stimulation of (1) long duration and (2) short duration, distribution of electrolytes, renal function, growth of young animals (rats), atrophy of adrenal and thymus glands of normal rats, and resistance to stress.

The physiologic processes associated with the first four items can be considered in relation to the site of action and the compounds or fraction from the adrenal cortex as shown in the accompanying table.

Britton and Silvette² have made an extensive study of the influence of the adrenal cortex on carbohydrate metabolism and have shown that glycogen in the liver and dextrose in the blood serum may be reduced to low levels after removal of the adrenal cortex. Long and Lukens,³ Evans⁴ and Grollman⁵ and others tried to demonstrate an effect on carbohydrate metabolism by extracts of the adrenal cortex through the use of phlorhizin, hypophysectomized-depancreatized animals and partially depancreatized rats. Rats which were partially depancreatized when young might have glycosuria after they had increased in weight, since the small amount of pancreas remaining

Structural formulas of adrenal compounds and of chemically related steroids.

could not furnish sufficient insulin for the adult animal. If these rats were adrenalectomized the glycosuria disappeared, and if they were given sodium chloride or sufficient cortical substance to maintain life, glycosuria did not reappear. At the time these experiments were carried out by Long and others, excessive amounts of cortical extract were not administered, since it did not appear necessary to give more than was required to

maintain life. Finally Long, Fry and Thompson⁶ showed that pure crystalline compound B, or corticosterone, produced glycosuria in partially depancreatized rats, and that the same results could be produced with large amounts of an extract from the adrenal cortex. No distinction was made by Long and his associates between the effect of the crystalline compound B and that of the whole extract. The evidence indicated that larger amounts of the whole extract were required to produce glycosuria than to maintain life, but this conclusion suggests the question whether the maintenance of life and the effect on carbohydrate metabolism are both due to the action of one vital hormone. This is one interpretation.

Another interpretation is that the adrenal cortex produces a series of compounds, some of which maintain life but have little effect on carbohydrate metabolism; other compounds have a marked effect on carbohydrate metabolism. In the extracts which were first used those compounds essential for maintenance of life were present in adequate amount, but there was a smaller quantity of those which affect carbohydrate metabolism. By the use of large amounts of extract

Physiologic Processes Associated with Glyconeogenesis, Muscle Activity, Distribution of Electrolytes and Renal Function in Relation to the Site of Action and the Compound or Fraction from the Adrenal Cortex

Primary Physiologic Activity	Primary Site of Action	Compounds or Fractions from Adrenal Cortex
Glyconeogenesis Muscle efficiency	Liver Muscles	Corticosterone and its derivatives with an atom of oxygen on C ₁₁
Distribution of electrolytes	Extracellular fluid Intracellular fluid	Desoxycorticosterone
Renal function	Kidney	Amorphous fraction

a sufficient amount of the compounds that affect glyconeogenesis was given to produce glycosuria.

Long, Katzin and Fry⁷ clearly demonstrated that the adrenal cortex increases the rate of glyconeogenesis and that the administration of pure crystalline compounds A, B and E resulted in the conversion of protein to carbohydrate. Recently Wells⁸ has shown wide divergence in the response of the various fractions of the adrenal cortex in respect to glyconeogenesis. Marked activity is possessed only by those compounds in which an atom of oxygen is attached at C₁₁. Desoxycorticosterone is much less efficient, and Wells has now shown that the amorphous fraction has little activity in respect to the conversion of protein to carbohydrate.

In 1936 Ingle⁹ published a method for the assay of cortical extracts based on the efficiency of muscles of adrenalectomized rats maintained with the extracts. The method has been used extensively during the past few years, and several compounds have been tested in regard to their effect on the efficiency of muscles stimulated over long periods. The work of Ingle¹⁰ shows

that only compounds which possess an oxygen atom at C₁₁ have a favorable influence and that desoxycorticosterone and the amorphous fraction, although highly active in other respects, have little effect on the efficiency of muscle.

In the summer of 1938 desoxycorticosterone, furnished by Professor T. Reichstein, was standardized in my laboratory and found to be at least six times more active than corticosterone in the maintenance of a normal level of blood urea and a normal condition in the adrenalectomized dog.¹¹ The observations of the early experiments have been confirmed and extended:¹² Desoxycorticosterone and its acetate will increase the concentration of sodium and decrease the concentration of potassium in the serum of normal rats more than any other product from the adrenal cortex.

At the same time Loeb and his associates¹³ found that the concentration of potassium in the dog can be depressed so low that paralysis can be produced. These striking effects are qualitatively different from those of the amorphous fraction, which is also concerned with the distribution of inorganic ions and water but which does not modify the normal distribution of electrolytes in the blood serum.¹²

During the past several years the compound most active in the maintenance of life after adrenalectomy has been designated as the vital hormone, as the salt and water hormone, as the essential hormone and as cortin. Investigation of the amorphous fraction which is left after removal of the crystalline compounds has indicated that, although on the basis of weight it is many times more efficient than any other product from the adrenal cortex, it nevertheless has little effect on glyconeogenesis and on efficiency of muscle. To designate this fraction as the essential hormone, therefore, is misleading, but for maintenance of renal function, which appears to be its primary effect, it shows an extraordinary degree of activity. Between 1 and 2 micrograms per kilogram of body weight is sufficient for the daily dose of an adrenalectomized dog.

In 1930 Hartman and Thorn¹⁴ showed that the growth of young rats was retarded by adrenalectomy, and they proposed a method for the standardization of extracts from the adrenal cortex on this basis. The method has since been used extensively to measure the activity of adrenal products, particularly by Grollman.¹⁵ It will be considered in more detail later, but here one may state that various fractions separated from the adrenal cortex have been shown to exert widely varying effects on the rate of growth.¹²

When an extract of the adrenal cortex is given to normal rats, the adrenal and thymus glands become atrophied within a week or ten days.¹⁶ Investigations

10. Ingle, D. J.: Personal communication to the author.

of this response by administration of the various fractions from the adrenal have shown that the effect is highly specific.

Atrophy of the adrenal is produced by corticosterone and those compounds with an oxygen atom at C_{11} , but the same amount of desoxycorticosterone given over the same interval does not produce atrophy of this gland; the thymus may be slightly hypertrophied.¹² Little if any effect is produced by the administration of enormous amounts of the amorphous fraction free from corticosterone and related compounds. The differences in the physiologic response to the various fractions from the adrenal cortex are perhaps most marked in the effects on growth and on atrophy of the adrenal and thymus glands. It is obvious that these results could be obtained only after separation of the extract into the various constituents, since each fraction produces such highly specific qualitative effects.

RESISTANCE TO STRESS

The influence of the various compounds of the adrenal cortex on resistance to stress as given in the preceding outline has been investigated only in part. Little is known in regard to the specific action of the various compounds on bacterial toxins or on histamine. A recent article by Perla and his associates¹⁷ indicates the favorable influence of a combination of sodium chloride and desoxycorticosterone in protection against histamine. Sodium chloride alone was more effective than desoxycorticosterone alone, but the best result was produced by the simultaneous administration of sodium chloride and desoxycorticosterone.

Some preliminary experiments indicate that the compounds with an oxygen atom attached at C_{11} have a favorable action against the toxic effects of thyroxine in adrenalectomized rats. This work will be continued in order to demonstrate the effect of other fractions in regard to resistance to thyroxine.

Jensen and Grattan¹⁸ have recently shown that corticosterone acetate will prevent convulsions after the injection of insulin. They also tried the whole extract, but since corticosterone acetate produced a favorable effect, it seems probable that corticosterone and related compounds in the whole extract are responsible for the increased resistance to insulin.

The striking response of adrenalectomized rats to phlorhizin when treated with various compounds and fractions of the adrenal cortex has been presented by Wells.⁸ It is highly significant that in this experimental condition, which is a sensitive index for glyconeogenesis, those compounds with an oxygen atom on C_{11} will permit the animal to live with a markedly increased rate of glyconeogenesis. Desoxycorticosterone and the amorphous fraction are not sufficient for maintenance of life under these conditions. A high percentage of adrenalectomized rats given desoxycorticosterone and phlorhizin died in convulsions.

Evans¹⁹ has shown that when the percentage of oxygen in the inspired air was reduced glycogen was deposited in the livers of normal rats but not in the livers of adrenalectomized rats. Since compounds with

an oxygen atom attached to C_{11} are involved in glyconeogenesis, it seems probable that these are the compounds responsible for the effects noted by Evans.

Selye and Schenker²⁰ have recently standardized the conditions first suggested by Hartman and his associates²¹ with regard to the influence of low temperature on adrenalectomized rats. Since it seemed of interest to investigate this test by the use of purified crystalline compounds and the amorphous fraction, adrenalectomized rats were subjected to low temperature, and it was found that as little as 16 micrograms of corticosterone, about 20 micrograms of compound E and about 13 micrograms of the amorphous fraction were sufficient to maintain life.²² This indicates that compounds with an oxygen atom on C_{11} and those found in the amorphous fraction were about equally active.

No experimental work has been carried out to determine the specificity of the various fractions with regard to the resistance of adrenalectomized rats to the injection of water.

STANDARDIZATION OF EXTRACTS OF THE ADRENAL CORTEX

The separation of the extract from the adrenal cortex into crystalline compounds and the amorphous fraction permits the identification of the compound responsible for the physiologic activity which has been the basis of each of the several methods that have been used for standardization. Among the many methods which have been proposed, six will be considered.

1. *Survival of Adrenalectomized Rats.*—This criterion is not specific for any compound or group of compounds. Even progesterone has been shown to increase the survival time of adrenalectomized ferrets,²³ and all of the compounds which possess any physiologic activity will permit the survival of adrenalectomized rats. The test does show the presence of some compound which can replace, at least in part, the secretion of the gland, but it is quite nonspecific for the identification of any particular compound.

2. *Growth of Young Rats.*—When the various fractions are administered to adrenalectomized young rats, those compounds with an oxygen atom on C_{11} retard or actually suppress the growth of the animals whereas the amorphous fraction will bring about an almost normal rate of growth, and desoxycorticosterone acetate may cause a gain in weight greater than that in a normal control.²⁴ Such a response is not a satisfactory criterion for the identification of any compound or group of compounds. With each solution tested, the rate of growth would be determined by the algebraic sum of the retarding influence of some of the compounds and the beneficial effects of others.

3. *Stimulation of Muscle.*—The Everse and de Fremery test²⁵ is based on the response of muscle to a short stimulation. The normal animal will react

characteristically both as to the duration of time and as to the vigor of the response to the stimulation. Adrenalectomized rats either will not respond at all or will respond in a much more limited way before the muscle is exhausted. It has been found that desoxycorticosterone acetate produces an effect about ten times greater than that of corticosterone.¹¹ Compound E has been shown to have little activity.²⁶ This criterion, therefore, has but little application, and a negative result does not mean lack of cortical activity, for activity may be indicated by other criteria.

4. *Prolonged Stimulation of Muscle*.—This test, which has been developed by Ingle²⁷ and is not related to the short stimulation of muscle, is highly specific for those compounds which have an oxygen atom attached to C₁₁. Compound E apparently is the most active; desoxycorticosterone manifests little activity, and the amorphous fraction in amounts many times that required for maintenance of a normal condition in an adrenalectomized dog is without effect. The high specificity of the compounds which have an oxygen atom attached to C₁₁ suggests that this test may be used for the quantitative determination of this group of compounds.

5. *Resistance to Low Temperature*.—This criterion is nonspecific, since corticosterone, compound E and the amorphous fraction have all been shown to be about equally active.

6. *Maintenance of Adrenalectomized Animals*.—This method of standardization²⁸ is not the same as number 1, since survival is not the basis of the test. That amount of material is determined which is required to hold the constituents of the blood within a normal range and to maintain the appetite, weight and normal appearance of the animal. The test becomes highly specific for the amorphous fraction, since this substance will maintain an adrenalectomized dog in excellent condition when as little as 1 to 2 microns per kilogram of body weight is used. Desoxycorticosterone is very active when tested with this method; about 15 micrograms per kilogram of body weight is required to maintain the adrenalectomized dog in normal condition.

FUNCTION OF THE ADRENAL CORTEX

The quantitative investigation of the physiologic response to several compounds separated from the adrenal cortex clearly shows that no one compound can produce all of the known effects of the extract. For glyconeogenesis and maintenance of the efficiency of muscle, corticosterone, compound E and their derivatives with an oxygen atom on C₁₁ are necessary. For the most marked effect on the distribution of electrolytes, desoxycorticosterone is required and for maintenance of normal renal function the amorphous fraction is the most efficient.

These three typical physiologic responses can all be produced, at least in part, by the single substance compound E. For this, however, 10 mg. is required in order to maintain normal renal function in the adrenalectomized dog.

If the structure of compound E is altered by the substitution of an atom of hydrogen instead of a hydroxyl

group on C₁₇, the compound is dehydrocorticosterone. Only 2.5 mg. of this is required to maintain normal renal function, and it is about as active as compound E in its effect on glyconeogenesis and on the efficiency of muscle. It does not modify the normal concentration of electrolytes in the serum.

If the structure of dehydrocorticosterone is modified by substitution of two atoms of hydrogen instead of an atom of oxygen at C₁₁, the compound is desoxycorticosterone. Three-tenths mg. of this compound will maintain normal function of the kidney, but the effect on glyconeogenesis is very small, and the compound has little effect on the efficiency of muscle. Comparison of these three compounds shows how intimately the physiologic effects are related to the chemical structure.

The close connection between the many physiologic effects as well as the interrelation between carbohydrate metabolism and the distribution of water and inorganic ions is well shown by nonspecific therapy, such as that with dextrose and a diet which contains a low concentration of potassium and a high concentration of sodium chloride and of sodium bicarbonate or sodium citrate. With this nonspecific therapy and without any product of the adrenal cortex it is possible to maintain adrenalectomized dogs in normal condition so far as the concentration of electrolytes in the serum is concerned.²⁹ Glycogen in the liver and dextrose in the blood are held within normal limits by the carbohydrate in the food. Such animals are to all appearances normal, but they do not possess ability to withstand stress. If the administration of sodium chloride is stopped even for a short time, they rapidly pass into a condition of crisis from adrenal deficiency.

Finally, it is possible to maintain dogs for at least seven days without food, provided sodium chloride is given in the drinking water and potassium salts are withheld. This result can be interpreted only by the primary importance of the regulation of the distribution and excretion of inorganic ions. If the changes in mineral metabolism, which have been well established, were secondary to disturbances in carbohydrate metabolism, it would be possible to maintain a normal condition by the administration of large amounts of dextrose, whether or not sodium chloride was supplied. It has been shown repeatedly by many investigators that this is not possible. On the other hand, when the loss of sodium and the retention of potassium in the adrenalectomized animal are corrected by the administration of large amounts of sodium chloride, glyconeogenesis can proceed at a rate sufficient to maintain the metabolism of carbohydrate within normal limits.

CONCLUSION

It has been shown that the adrenal cortex does not elaborate any single substance which can be described as the vital hormone of this gland. An extract of the adrenal cortex contains a surprisingly large number of closely related steroid derivatives which have specific effects, qualitatively different one from the other. Substitution therapy in adrenalectomized animals is inadequate unless the compounds which influence glyconeogenesis and the efficiency of muscles are given together with the compounds that influence renal function and the distribution of water and electrolytes.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL SULFADIAZINE

THE COUNCIL HAS GIVEN CONSIDERATION TO FURTHER SULFONAMIDE DERIVATIVES; IN PARTICULAR, THE 2-SULFANILAMIDOPYRIMIDINE HOMOLOGUE OF SULFANILAMIDE, FOR WHICH IT HAS RECOGNIZED THE NON-PROPRIETARY NAME SULFADIAZINE. IN THIS CONNECTION THE COUNCIL HAS CONSIDERED A PRELIMINARY REPORT ON SULFADIAZINE PREPARED BY DR. PERRIN H. LONG. THE COUNCIL ADOPTED THIS REPORT FOR PUBLICATION AND EXPRESSES ITS GRATITUDE TO DR. LONG FOR THE PREPARATION OF THE FOLLOWING STATEMENT.

OFFICE OF THE COUNCIL.

SULFADIAZINE

THE 2-SULFANILAMIDOPYRIMIDINE ANALOGUE OF SULFANILAMIDE

PERRIN H. LONG, M.D.
BALTIMORE

Recently, Roblin and his associates¹ have described the preparation of certain heterocyclic sulfonamide compounds. Among them were 2-sulfanilamido-pyrimidine, 2-N⁴-acetylsulfanilamidopyrimidine, 2-sulfanilamido-4-methylpyrimidine, 2-N⁴-acetylsulfanilamido-4-methylpyrimidine and 4-sulfanilamidopyrimidine. One of these compounds, 2-sulfanilamidopyrimidine, to which the name of sulfadiazine has been given in order to prevent confusing this pyrimidine derivative with the pyridine homologue of sulfanilamide, has been distributed for experimental use and clinical investigation. The name sulfadiazine has been accepted by the Council on Pharmacy and Chemistry.

Feinstone and his collaborators² have made an excellent and complete report on the toxicity, absorption and chemotherapeutic activity of this compound in experimental animals. As regards the acute toxicity of sulfadiazine for mice, based on blood concentrations, they found that the L. D. 50 (i. e., the blood concentration of the drug which kills 50 per cent of the mice) lay between 175 and 200 mg. per hundred cubic centimeters. In chronic toxicity studies on monkeys, in which comparisons were again made on the basis of blood concentrations, they observed that sulfadiazine produced less tissue damage than did sulfathiazole or sulfapyridine. An interesting point which was brought out in this study was that the blood concentrations resulting from given doses of sulfadiazine in monkeys and in mice were about four times as high as those resulting from comparable doses of sulfapyridine or sulfathiazole and that the drug existed in the blood primarily in the "free" form because the acetyl derivative appeared to be readily excreted in the urine. They found that this compound had a high degree of therapeutic activity in experimental pneumococcic, hemolytic streptococcus and staphylococcic infections in mice and that it was very effective in the treatment of experimental Friedländer's bacillus infections in mice.

We have been able to confirm the observations of Feinstone and his associates in respect to the toxicity and absorption of sulfadiazine in mice. We have also tested the therapeutic effect of these compounds on

experimental hemolytic streptococcus, pneumococcic, staphylococcic, *Clostridium welchii*, *Cl. septicum* and *Cl. oedematiens* infections in mice. Our experiments lead us to believe that sulfadiazine is a somewhat less effective therapeutic agent than sulfanilamide in experimental streptococcic infections in mice, this observation being based on comparable tests in which the blood concentrations of the two drugs were set at approximately the same levels in the experimental animals.

In type I pneumococcus infections in mice, sulfadiazine proved to be slightly less effective than sulfathiazole or sulfapyridine when tested under comparable conditions. In experimental staphylococcic infections in mice, sulfadiazine was equal, if not slightly superior, to sulfathiazole as a therapeutic agent. In infections in mice produced by the intramuscular injection of *Cl. welchii* or *Cl. septicum*, sulfadiazine was an effective chemotherapeutic agent whether administered by oral or local routes. In these particular experiments sulfadiazine showed good chemotherapeutic activity, with sulfathiazole coming next and sulfapyridine as a fair third, while sulfanilamide exhibited practically no activity. In *Cl. oedematiens* infections in mice, we were unable to demonstrate a significant therapeutic effect with any of the four compounds. Klinefelter,³ working in our laboratories, has shown that sulfadiazine is a more effective chemotherapeutic agent in experimental *Escherichia coli* infections in mice than is sulfathiazole.

Plummer and Ensworth⁴ have reported that sulfadiazine is rapidly absorbed into the blood, that the proportion of acetyl sulfadiazine in the blood is small, that the concentration of the drug in the blood falls rather slowly after the drug has been discontinued, and that most of the ingested sulfadiazine is excreted in the urine. They noted one toxic reaction (a morbilliform rash) in twelve patients treated with the drug.

My associates and I have carried out studies on the absorption, distribution and excretion of sulfadiazine in man. Our studies (contrary to those of Plummer and Ensworth) indicate that the drug is somewhat less rapidly absorbed from the gastrointestinal tract than are sulfanilamide, sulfapyridine and sulfathiazole. In the blood the ratio of the "free" and conjugated fractions of the drug is frequently less than that which has been previously noted for sulfanilamide. Sulfadiazine appears to be excreted somewhat less rapidly than is sulfanilamide or sulfapyridine when renal function is normal. In the urine about a third of the drug exists in the acetylated or conjugated form. The relatively small amounts of acetylsulfadiazine found in the blood are due to the fact that this compound is quite easily excreted in the urine when kidney function is normal.

While our experience has been limited to date, it seems that sulfadiazine passes over into the spinal fluid in concentrations of from two thirds to four fifths of those which exist in the blood. An interesting feature of this drug is the relative ease with which it is possible to maintain adequate concentrations of it in the blood of human patients, and, as a matter of fact, care must be taken to follow the blood levels of sulfadiazine in order to prevent unnecessarily high concentrations of the drug.

It is too early to make a statement regarding the relative clinical therapeutic merits of sulfadiazine, sulfanilamide, sulfapyridine and sulfathiazole. However, our experience to date leads us to believe that sulfadiazine

2. Feinstone, W. H.; Williams, R. D.; Wolff, R. T.; Huntington, Evelyn, and Crossley, M. L.: The Toxicity, Absorption and Chemotherapeutic Activity of 2-Sulfanilamidopyrimidine (Sulfadiazine), *Bull. Johns Hopkins Hosp.* **67**: 427 (Dec.) 1940.

3. Klinefelter, H. F.: Personal communication to the author.

4. Plummer, Norman, and Ensworth, H. K.: Absorption and Excretion of Sulfadiazine, *Proc. Soc. Exper. Biol. & Med.* **45**: 734 (Dec.) 1940.

is slightly less effective than sulfapyridine or sulfathiazole in the treatment of pneumococcal pneumonia in human beings and that it is of definite value in the treatment of hemolytic streptococcus and staphylococcal infections in man. We have noted in the course of clinical experiments with sulfadiazine that there is very little nausea and vomiting produced by this drug. Drug fever and drug rash have been rare. We have noted 2 instances of leukopenia in 125 patients who have been treated with the drug. Scleral and conjunctival injections have been observed in 2 patients. Sulfadiazine does not cause a fall in the carbon dioxide combining power of the plasma. We have not observed any evidence of renal injury up to the present time. In 1 patient, ill with pneumonia, who on admission to the hospital was found to be suffering from a rather severe acute renal complication incident to his pneumonia, the administration of full doses of sulfadiazine resulted in a blood concentration of 25 mg. per hundred cubic centimeters of the "free" drug within seventy-two hours. Although this patient's renal function was practically zero as measured by the phenolsulfonphthalein test, both the "free" and the acetylated forms of the drug were gradually excreted over a period of days without any evidence of an increase in kidney damage. During the period of the excretion of the drug the patient's renal function was very poor, as was evidenced by the observation that at the time when the drug had been eliminated from the blood the phenolsulfonphthalein test showed a 15 per cent excretion of the dye in two hours. It is to be expected that sulfadiazine will produce certain of the toxic reactions previously described as occurring in the course of treatment with sulfanilamide and other of its derivatives. Our experience up to the present time leads us to believe that sulfadiazine produces fewer toxic manifestations than either sulfanilamide, sulfapyridine or sulfathiazole.

As yet there is insufficient information at hand on which to establish adequate standards of dosage with sulfadiazine. For adult patients ill with pneumonia, it has been our custom to prescribe an initial dose of 4 Gm. of sulfadiazine, to be followed at four hour intervals with 1 Gm. for six doses. The dosage schedule is then changed to 1 Gm. every six hours and is so continued until the patient's temperature has been normal for seventy-two hours. In the majority of patients these doses will produce concentrations of from 6 to 9 mg. per hundred cubic centimeters of the drug in the blood within the first twenty-four hours of its administration. Then as therapy is continued with the lesser amount of sulfadiazine the concentrations of the drug in the blood will tend to fall to between 4 and 7 mg. per hundred cubic centimeters. We have also noted in patients ill with chronic hemolytic streptococcus or staphylococcal infections, such as osteomyelitis, that the administration of 0.05 Gm. per kilogram of body weight of sulfadiazine as the total daily dose will produce concentrations of around 5 mg. per hundred cubic centimeters in the blood. In such patients it is advisable to divide the total daily dose into four parts and to administer them at six hour intervals.

The evaluation of this new chemotherapeutic agent will necessitate extensive experimental and clinical investigation in order to determine its true value. Until the time when such data are available, it is to be hoped that preliminary enthusiasms will not outrun the common sense which we have gained as a result of our experiences with sulfanilamide and its other derivatives during the past five years.

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT.
OFFICE OF THE COUNCIL.

The Council on Pharmacy and Chemistry of the American Medical Association records with deep sorrow the death, March 1, 1941, of

Charles Wallis Edmunds

On the afternoon of Saturday, March 1, 1941, death came suddenly to Charles Wallis Edmunds, professor of pharmacology at the Medical School of the University of Michigan.

Dr. Edmunds was born in Bridport, Dorset, England, on Feb. 22, 1873 and came to the United States ten years later. He graduated from the Medical School of the University of Michigan in 1901 and shortly after he began his work in pharmacology as an assistant to Dr. Arthur R. Cushny. Dr. Edmunds was made professor of pharmacology in 1907, as successor to Dr. Cushny, and continued in that position until his death. From 1911 to 1921 he was secretary and from 1918 to 1921 assistant dean of the faculty in the medical school. From 1935 to 1939 Dr. Edmunds was a member of the executive committee of the medical school, and since 1937 he had served as a member of the executive board of the graduate school.

Dr. Edmunds always had a great interest in the United States Pharmacopeia, and he had served on the Revision Committee since 1910. From 1920 he had been a member of the executive committee, a vice chairman since 1930, chairman of the antianemia products advisory board since 1935, and chairman of the committee on biologic assays since 1920. At the 1940 United States Pharmacopeial Convention Dr. Edmunds was chosen president.

He was appointed to the Council on Pharmacy and Chemistry in February 1921 and had been reappointed at regular five year intervals since that time. One of his chief services was the chairmanship of the Committee on Therapeutic Research, which had been in his hands since 1935. For some years he was the referee for endocrine preparations and was instrumental in framing the Council's pronouncements as this field of therapy began its subsequent extensive development. For many years he had been the referee for ergot preparations, and the New and Nonofficial Remedies' chapter on ergot preparations took its definitive form under his refereeship. For approximately fifteen years he was referee for vasoconstrictors. He was always prompt and efficient in his attention to Council duties and brought to the deliberations of the Council the wisdom and judgment of an enlightened and well seasoned intelligence.

For over ten years Dr. Edmunds had been a member of the Committee on Drug Addiction of the National Research Council and at the time of his death was a member of the executive committee of the Division of Medical Sciences of the National Research Council. His wide knowledge in the field of drug assays resulted in his having been made a member of the international committee on drug standardization of the health committee of the League of Nations in 1925. In 1929-1930 he was chairman of the Section on Pharmacology and Therapeutics of the American Medical Association. He was a past president of the American Society for Pharmacology and Experimental Therapeutics and a member of the American Physiological Society, the Association of American Physicians and the Society for Experimental Biology and Medicine. In the field of pharmacology he was a sound contributor toward the advancement of knowledge. With Dr. Arthur R. Cushny he wrote the "Laboratory Guide in Pharmacology," and with Prof. J. A. Gunn of Oxford, England, he recently revised Cushny's textbook on "Pharmacology and Therapeutics." For thirty years, he served on the editorial board of the *Journal of Pharmacology and Experimental Therapeutics*.

However, it will not be wholly through his scientific work that his students, colleagues and friends will remember him. The following tribute was written by a member of the Council who in earlier years was one of Dr. Edmunds' students:

Dr. Edmunds was a genial, understanding teacher and friend, who could be depended on under all conditions. Those of us who were his students remember our first fears when entering

our pharmacology laboratory period, but the kindness and interest of Dr. Edmunds not only in our laboratory problems but also in respect to all the difficulties which beset the medical student soon set these fears at rest. We shall always remember his well known lecture on the pharmacology and therapeutics of gold, especially the climax of the lecture, in which Dr. Edmunds would state so amusingly that nothing was more effective for soothing the itching palm. His colleagues on the Council on Pharmacy and Chemistry will miss his kindly penetrating criticisms, his shrewd analysis of various claims for therapeutic merit and his ability to bring about harmony and compromise in difficult situations. Those of us who worked with him and knew him personally have lost a true friend.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

OFFICE OF THE COUNCIL.

BISMUTH SUBSALICYLATE (See New and Non-official Remedies 1940, p. 150):

The following products have been accepted:

The Lakeside Laboratories, Inc., Milwaukee.

Ampules Bismuth Subsalsicylate in Oil with Chlorobutanol, 1 cc.: Each cubic centimeter contains bismuth subsalsicylate 0.13 Gm. (2 grains) suspended in a neutral vegetable oil with 3 per cent chlorobutanol.

Vials Bismuth Subsalsicylate in Oil with Chlorobutanol, 30 cc.: Each cubic centimeter contains bismuth subsalsicylate 0.13 Gm. (2 grains) suspended in a neutral vegetable oil with 3 per cent chlorobutanol.

Vials Bismuth Subsalsicylate in Oil with Chlorobutanol, 60 cc.: Each cubic centimeter contains bismuth subsalsicylate 0.13 Gm. (2 grains) suspended in a neutral vegetable oil with 3 per cent chlorobutanol.

NEO-IOPAX (See New and Nonofficial Remedies, 1940, p. 304).

The following dosage form has been accepted:

Manufactured by Schering Corp., Bloomfield, N. J. U. S. patent applied for. U. S. trademark 297,925.

Solution Neo-Iopax, 30 cc. Vials: Each vial contains neo-iopax, 15 Gm. dissolved in sufficient sterile distilled water to make 30 cc.

SULFAPYRIDINE (See New and Nonofficial Remedies, 1940, p. 494).

The following dosage form has been accepted:

Tablets Sulfapyridine-Merrell, 0.5 Gm. (7.7 grains).

Prepared by the Wm. S. Merrell Co., Cincinnati.

THEOBROMINE SODIUM ACETATE (See New and Nonofficial Remedies, 1940, p. 554).

The following dosage form has been accepted:

Tablets Theobromine with Sodium Acetate, 7½ grains.

Prepared by The Smith-Dorsey Co., Inc., Lincoln, Neb.

BACTERIAL VACCINE MADE FROM THE TYPHOID BACILLUS AND THE PARATYPHOID "A" AND "B" BACILLI (See New and Nonofficial Remedies, 1940, p. 463).

The Upjohn Company, Kalamazoo, Mich.

Typhoid Paratyphoid Mixed Vaccine (See New and Nonofficial Remedies, 1940, p. 466): Also marketed in packages of six 2½ cc. vials containing in each cubic centimeter 1,000 million killed typhoid bacilli, 750 million each of killed paratyphoid A and paratyphoid B bacilli.

METHENAMINE (See New and Nonofficial Remedies, 1940, p. 266).

METHENAMINE-MERRELL.—A brand of methenamine-U. S. P.

Manufactured by the Wm. S. Merrell Company, Cincinnati. No U. S. patent or trademark.

Methenamine Tablets-Merrell, 5 grains.

Methenamine Tablets-Merrell, 7½ grains.

SULFATHIAZOLE (See THE JOURNAL, Jan. 25, 1941, p. 308).

Sulfathiazole-Abbott.—A brand of sulfathiazole-N. N. R.

Manufactured by Abbott Laboratories, North Chicago, Ill. No U. S. patent or trademark.

Tablets Sulfathiazole-Abbott, 0.5 Gm. (7.7 grains).

Tablets Sulfathiazole-Abbott, 0.25 Gm. (3.85 grains).

PENTOBARBITAL-SODIUM (See New and Nonofficial Remedies, 1940, p. 128).

The following dosage form has been accepted:

Pentobarbital-Sodium Tablets, 1½ grains.

Prepared by the Wm. S. Merrell Co., Cincinnati.

THEELOL-P. D. & CO. (See New and Nonofficial Remedies, 1940, p. 371).

The following dosage form has been accepted:

Kapsels Theelol, 0.24 mg.: Each kapsel (sealed gelatin capsule) contains 0.24 mg. theelol.

Council on Foods and Nutrition

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
FRANKLIN C. BING, Secretary.

The Council on Foods and Nutrition of the American Medical Association records with deep sorrow the death, on February 1, of

Mary Swartz Rose (Mrs. Anton R. Rose).

Born at Newark, Ohio, on Oct. 31, 1874, the daughter of Judge Hiram E. Swartz; Mary Swartz Rose graduated from Denison University in 1901, studied home economics for a year at Mechanics Institute, Rochester, N. Y., and then entered Teachers College, Columbia University, where she received the degree of Bachelor of Science in 1906. She then studied at Yale University under Prof. Lafayette B. Mendel and received a Ph.D. degree in 1909. Her subsequent academic career was spent at Teachers College, where she held successively the posts in instructor of nutrition (1909-1910), assistant professor (1911-1918), associate professor (1918-1923) and professor (1923-1941).

Mrs. Rose was one of the outstanding teachers of her time. Through her classes at Teachers College she came to exert a wide influence on the development of nutrition and the teaching of this science in many institutions throughout the country. Through her writings, notably her books "Feeding the Family," "Foundations of Nutrition," "Everyday Foods in War Time" and "Teaching Nutrition to Boys and Girls," she brought her talents as a writer effectively to bear on the problem of education of the general public in matters concerning foods and nutrition. In the midst of these many activities she also proved that she could be a productive scholar adding to the sum total of scientific knowledge in this field. These contributions are recorded in a long list of papers reporting researches carried out in her laboratory with many students and colleagues. Mrs. Rose also played a part in organizing research workers in nutrition, being one of the founders of the American Institute of Nutrition. She served this organization as vice president in 1936 and president in 1937. Her further activities in this connection included service as a member of the editorial board of the *Journal of Nutrition*.

Because of her unusual qualities, she was also called on to render important public services. In 1918-1919 she held the position of Deputy Director of the Bureau of Conservation of the Food Administration, in 1935 she was appointed a member of the nutrition commission of the health organization of the League of Nations and in 1940 Dr. Rose was chosen one of a national group of five to serve as advisers on nutrition to the Council of National Defense and consultants to the committee on food and nutrition of the National Research Council. She was first appointed a member of the Council on Foods of the American Medical Association in 1933 and in this capacity rendered unstinting service for many years.

From this brief statement it is evident why Dr. Rose should have been elected to membership in the Council on Foods. To the Council's deliberations she brought a wide experience that touched not merely the academic sphere of interest but the general public welfare and education of both the public and the food industry, matters of great importance in relation to the work which the Council was established to perform. These counsels were effectively rendered because they came from one who was imbued with much personal charm.

THE HUMAN FACTOR IN MOTOR VEHICLE ACCIDENTS: PHYSICAL OR MENTAL DISABILITIES

The operation of a motor vehicle under the trying conditions of highway traffic today demands that the driver exercise constant vigilance and care, that he possess normal reactions, responses and judgment and that he be not so physically or mentally disabled as to be unable at any given time to respond to unusual situations. The use of any lower standard by any particular driver is a potential menace to the public. Indeed, most of the appalling present day traffic toll is attributed by some to such failure of the human factor.

Much consideration has been given by private citizens and agencies, by public officials and legislative bodies and by committees to the problem of highway safety. The human factor has not been overlooked; attempted means of control have been adopted, but unfortunately there are still almost countless instances of failure. All the states in the Union but three appear now to have laws prohibiting the operation of a motor vehicle except by a person licensed to do so by the appropriate state agency. The theory of these laws is that the applicant for a license to drive must demonstrate mastery of the simple traffic rules of the state, mechanical ability to drive, and physical and mental capacity to do so. The enforcement of these laws, however, has not as yet insured that safe drivers only are behind steering wheels. Possibly some of the more significant reasons for the failure of the laws to produce the desideratum are that (1) most of the laws permit the licensing without examination, or after a most cursory examination, of all persons who have operated a motor vehicle prior to the enactment of the particular law; (2) while an examination may indicate that a prospective licensee can operate a car safely, no test can ascertain the operator's willingness or constant endeavor in the future to do so, and (3) while most laws prohibit the issuance of a license to one who by reason of physical or mental disability is or may be

unable to operate a motor vehicle safely, the provision is largely ineffective unless the applicant is subjected to a competent medical examination. Few if any of the state laws contain adequate provisions in this respect.

Probably the failure of the human factor is due generally to the driver's relaxation of his willingness or endeavor constantly to drive safely. Carelessness, inattention or a willingness to drive while under the influence of alcoholic liquors or drugs to such an extent as to affect reactions, responses and discretion are frequently the basis of catastrophe.

The problems, however, with respect to those accidents attributable to physical or mental disabilities of the driver have not received the consideration that their importance justifies. Present drivers' licensing laws and other related laws are not sufficient to insure that operators of motor vehicles are mentally and physically capable of assuming control of such potentially lethal instruments as motor vehicles. These particular problems can never even approach solution until each applicant for a driver's license is subject to a thorough medical examination.

Most of the drivers' licensing laws prohibit the issue of a license to a person when the administrative authority "has good cause to believe that such person by reason of physical or mental disability would not be able to operate a motor vehicle with safety on the highways" or when it "has good cause to believe that the operation of a motor vehicle on the highways by such person would be inimical to public safety or welfare." Clearly, many disabilities that render a person an unsafe driver are not recognizable by the cursory examination now conducted by lay officials and might be discovered by a reasonably thorough medical examination. As matters now stand, a license may be refused for the reasons just stated or if, after the issuance of a license, a disability that renders the holder an unsafe driver is brought to light, the license may be revoked, suspended or canceled. Generally, however, such disabilities are brought to the attention of the licensing agency only after the occurrence of an accident.

To ascertain what persons are unfit mentally or physically to drive, it may be necessary to go further than merely to provide for the medical examination of applicants for drivers' licenses. Indeed, it may become necessary to require physicians and other persons to report instances of defects coming to their knowledge which might make another person unsafe as a driver of a motor vehicle. This suggested type of law may be necessary with respect to such conditions as epilepsy, which might not be ascertained even by a reasonably competent medical examination. As the law now stands in at least seventeen states a person who has been adjudged to be epileptic may not be licensed to drive and in at least twenty-three states, including the states just referred to, may not be licensed if he has a physical or mental defect causing a lack of reasonable

driving control. Presumably epilepsy would be so classified. The states referred to permit the revocation of a license for the reasons stated. Unfortunately, however, as intimated before, the licensing agency has no means of ascertaining such a disabling condition as epilepsy unless by some chance it learns of an accident occurring while the driver was in an epileptic fit. In but two states, so far as is known, is epilepsy a reportable disease. In California a law has recently been enacted¹ requiring all physicians to report to the local health officer concerning "every person diagnosed as a case of epilepsy or similar disorders characterized by lapses of unconsciousness." The local health officer must transmit the report to the state department of health, which in turn passes on the information to the state department of motor vehicles "in enforcing the provisions of the vehicle code of California." In New Jersey a report is required of the attending physician or other person having knowledge of the facts to agencies that eventually pass the report on to the state department of health—and not to the agency administering the drivers' licensing law. Laws requiring the reporting of such defects, together with laws requiring prospective drivers to submit to medical examinations to ascertain the presence of disabling mental and physical defects, should have an appreciable effect in making our highways safer.

FAT METABOLISM IN DIABETES MELLITUS

The ketonuria observed in the depancreatized dog and in the diabetic human being was early believed to be related to an altered carbohydrate metabolism. Hirschfeld¹ in 1895 showed that the factor common to all conditions of ketosis was the lack of carbohydrate in the food or, as in the diabetic patient, from his metabolism. The fact that ketosis appeared to be definitely related to carbohydrate starvation led many investigators to study the quantitative relationships between dietary carbohydrate and fat, on the one hand, and the degree of ketosis, on the other. From such investigations, notably by Zeller² and by Lusk³ and his pupils, arose the hypothesis that the burning of carbohydrate in the body in some way prevents the appearance of ketosis and that carbohydrate is therefore "antiketogenic." The aphorism "fats, or acetone bodies, burn in the fires of carbohydrates" became the classic textbook description of fat metabolism in diabetes mellitus. From this arose the concept of ketogenesis and antiketogenesis. Rather striking confirmation of this hypothesis was provided in 1921 by the demonstration⁴ that the oxidation of acetoacetic acid by

hydrogen peroxide in alkaline solution is catalyzed *in vitro* by the presence of dextrose; quantitative relationships between the amount of dextrose oxidized and the quantity of fatty acid burned were suggested on the basis of these experiments. Examination of the literature and calculations based on available clinical and experimental data led to the conclusion⁵ that a striking correlation prevails between the extent of ketosis in experimental animals and in patients and the ratio of ketogenic to antiketogenic substances in the diet. From this and similar work, theoretically practical ratios for the dietary regulation of clinical ketosis, with particular reference to diabetes mellitus, were established.

Since 1928, however, evidence has accumulated which necessitates a complete revision of the concept of an obligatory coupling of the oxidation of carbohydrate and ketones. In that year Chaikoff and Soskin⁶ demonstrated that injected acetoacetate was utilized by the muscles of the diabetic as well as by the normal eviscerated dog. More recently Blixenkrone-Møller⁷ perfused the hind limbs of normal and diabetic cats and showed an active utilization of ketones by muscle. The extent of utilization was greatly increased in contracting muscle and it was concluded that ketone oxidation might furnish a large portion of the total energy requirements. Similar utilization and oxidation of ketones have been demonstrated in the peripheral tissues⁸ of the intact rat, following phlorhizin or anterior pituitary administration, and in the muscle of both the normal and the depancreatized cat.⁹ In the latter animal, obviously, the oxidation of ketones by muscle must be independent of the presence of insulin.

The oxidation of ketones in the peripheral tissues is apparently a process furnishing energy for the organism and taking place both in normal and in diabetic animals. The utilization of ketones by the tissues of diabetic animals, in the absence of normal oxidation of carbohydrate, clearly emphasizes the independence between the oxidation of carbohydrate and that of ketones. The clinical data which have been cited to support the obligate coupling of fat and carbohydrate metabolism have recently been reexamined and evaluated by Stadie,¹⁰ who concluded that there is no significant relation between the ketone bodies utilized and the "antiketones" oxidized. This investigator postulates the following hypothesis of fat metabolism in diabetes mellitus as fulfilling the statistically significant facts derived from the clinical data: "Up to a certain level fat metabolism is complete and there is no ketonuria. Beyond this level fat metabolism is incomplete and part of the fat catabolized is excreted in the

form of ketone bodies." Fat metabolism and, as a consequence, ketogenesis are accentuated in conditions of impaired carbohydrate utilization, diminished carbohydrate supply or accelerated fat and protein metabolism due to the injection of anterior pituitary extracts. Any of these circumstances augments ketone body production and is a manifestation of the increased demands which the body makes on the metabolic processes involving fat. The ketonemia and ketonuria which may result are a consequence of the failure of ketone utilization in the peripheral tissue to keep pace with the increased ketone production in the liver and, perhaps to a limited extent, in the muscles. Relationships between carbohydrate and fat metabolism which were formerly considered obligate are therefore related only in that both types of metabolism exist in the normal person, who derives his energy from both carbohydrate and fat oxidation, whereas the diabetic person, with impaired utilization of the former process, must necessarily depend almost wholly on the latter reaction for his energy. Under these circumstances ketone body production exceeds utilization, and ketonemia and ketonuria are evident. The administration of insulin renews the possibility of completing carbohydrate oxidation; the amount of fat which must be processed becomes less and production of ketone bodies diminishes.

THE DISTINGUISHED SERVICE MEDAL

The Distinguished Service Medal of the American Medical Association will be presented for the fourth time at the opening meeting at the annual session of the Association in Cleveland, June 2. The method of selection of the recipient of the Distinguished Service Medal is defined in the By-Laws of the Association. Any Fellow of the Association may submit nominations and these should now be sent promptly, together with a record of the scientific services of the nominee, to the chairman of the Committee on Distinguished Service Awards, Dr. Alfred A. Walker, 2250 Highland Avenue, Birmingham, Ala., or to Dr. Olin West, Secretary of the American Medical Association, 535 North Dearborn Street, Chicago. Of the nominations received by the committee, five will be submitted to the Board of Trustees of the Association and from these the board will select three to be submitted to the House of Delegates. Immediately on submission of the nominations of the Board of Trustees, the House of Delegates by vote selects the one to whom the Distinguished Service Medal will be presented on the evening of the following day. Obviously an extended list of distinguished physicians nominated by Fellows of the Association for this award will enable the committee, the Board of Trustees and the House of Delegates, all of whom participate in the selection, to determine for 1941 a recipient whose nomination again will reflect favorably not only on himself but on the Association.

REGISTRATION UNDER HARRISON NARCOTIC ACT

Annually for many years *THE JOURNAL* has given timely warning to physicians that reregistration under the Harrison Narcotic Act must be effected on or before July 1 of each year. Despite these repeated warnings some physicians continue to overlook this requirement and later are subjected to an inconvenience and to the necessity of paying the penalty for their tardiness. One physician who became involved because of his failure to reregister in time actually complained because *THE JOURNAL* had not forewarned him. Now *THE JOURNAL* again calls attention to the fact that on or before July 1 every physician registered under the Harrison Narcotic Act or under the Marihuana Tax Act must reregister with the collector of internal revenue of each district in which he maintains an office or a place for the treatment of patients. Failure to reregister within the time allowed by law adds a penalty of 25 per cent to the amount of the annual tax payable at the time of registration and in addition makes the physician in default liable to a fine not exceeding \$2,000 or to imprisonment for not exceeding five years or both. The Commissioner of Internal Revenue has given some negligent or recalcitrant physicians the choice between paying substantial sums by way of compromise in lieu of the penalties for their offenses or, as an alternative, accepting criminal prosecution with resultant publicity and liability to fines and possible imprisonment. This practice on the part of the Commissioner of Internal Revenue is warranted by law. In each instance, moreover, it is an act of grace on the part of the Commissioner, for he might have instituted criminal prosecutions without allowing the offending physicians any choice in the matter. If the course that the Commissioner has followed does not produce the desired promptness in registration, there is no recourse other than criminal prosecution to attain the result.

MEDICINALS IN CHINA

War frequently brings about unlooked for changes. One of these is the reversal in attitude by the masses of the rural population in China toward Western medicines. The customary antipathy in this respect has been largely dispelled; Chinese manufacturers of medicinals are looking forward to an expansion of their trade in the future. The opening of transportation routes to the interior resulting partly from the exigencies of war also is playing a part in increasing trade in medicinals in China. The greater part of China's requirements in pharmaceutical, medicinal and biologic preparations are met by imports the approximate value of which reached \$5,775,000 in 1939.¹ Nevertheless, the domestic industry has expanded and within the past year great progress has been made in the manufacture of biologic preparations, though 70 per cent of the ingredients are still imported. The fact that eight large manufacturing establishments in Shanghai are producing proprietary medicines, vaccines, serums, antiseptics, anesthetics and general hospital supplies gives an idea of the activity in this field.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

DIAGNOSIS AND TREATMENT OF THE VENEREAL DISEASES

CIRCULAR LETTER NO. 18

Prepared by the Subcommittee on Venereal Diseases of the Committee on Chemotherapeutic and Other Agents

An outline of the use of chemotherapeutic agents in the treatment of infectious diseases and other infections as recommended by the Committee on Chemotherapeutic and Other Agents and its Subcommittee on Infectious Diseases of the Division of Medical Sciences, National Research Council, was published in Circular Letter No. 81, dated Dec. 5, 1940.

The following outline on the diagnosis and treatment of the venereal diseases records briefly the opinions and recommendations of that committee and its subcommittee on venereal diseases. The data on which this circular letter is based have been prepared by the Subcommittee on Venereal Diseases and approved by the Committee on Chemotherapeutic and Other Agents.

The instructions contained in paragraph 29, Circular Letter No. 1, Jan. 2, 1940, in conflict with this circular letter, are rescinded.

The Subcommittee on Venereal Diseases, chairman, J. E. Moore, is composed of J. E. Moore, associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore; Edwin P. Alyea, associate professor of surgery, Duke Medical School, Durham, N. C.; Charles W. Clarke, American Social Hygiene Association, New York; Oscar F. Cox Jr., secretary, American Neisserian Medical Society, Boston; J. F. Mahoney, Senior Surgeon, United States Public Health Service, Venereal Disease Research Laboratory, Staten Island, N. Y., and John H. Stokes, professor of dermatology and syphilology, University of Pennsylvania School of Medicine, Philadelphia.

Because of the rapid development of chemotherapeutic agents, it is likely that some of these recommendations will have to be modified from time to time. Certain measures other than chemotherapeutic are described where appropriate. These recommendations are published as a general guide for medical officers and are to be used at their discretion, with due consideration of all other factors which may be presented by each individual case. It is not intended that they should be used to the exclusion or neglect of other indicated therapeutic or nursing procedures.

Treatment of the following diseases is discussed:

1. Gonorrhea.
2. Syphilis.
3. Chancroidal infection.
4. Lymphogranuloma venereum.
5. Granuloma inguinale.

GONORRHEA

A. Diagnosis in Males.—1. A diagnosis of gonorrhea must not be made in the absence of laboratory confirmation (although in emergencies, when laboratory

facilities are not available within twenty-four hours, patients with acute purulent urethral discharge should be started on treatment for gonorrhea).

2. Acute gonorrhea (anterior urethritis) is diagnosed on the basis of a purulent urethral discharge with positive gram staining for gonococci.

3. Chronic gonorrhea (posterior urethritis, prostatitis, seminal vesiculitis, arthritis) may be diagnosed on the basis of the results of gram staining of urethral discharge or of prostatic secretion revealing gonococci or by culture of appropriate body fluids.

4. Gonorrheal ophthalmia is an acute purulent conjunctivitis, rapidly progressing to involve other external coats of the eye, the secretion revealing gonococci by gram staining.

B. Diagnosis in Females.—1. Definite diagnosis of early gonorrhea in women is more difficult than in men.

2. Diagnosis should be based on: (a) History: (1) Symptoms (dysuria, vaginal discharge, vulvar pruritus, pelvic inflammation, acute arthritis). (2) Exposure to known gonorrhea.

(b) Clinical examination, especially abdominal, pelvic and rectal (especially important in cases of chronic gonorrhea).

(c) Gram staining of secretion from the urethra, Bartholin's glands, the cervix and the rectum. (Caution: The normal genital flora may contain organisms which closely resemble gonococci.)

(d) Culture, which should always be performed if smear findings are not corroborated by history and physical examination.

C. Treatment of Acute Gonorrhea in Males or Females.—1. Local treatment (for males). (a) Local treatment (irrigations, instillations or other procedures) should not be used in any form except for patients resistant to the sulfanilamide compounds or for those with complications (posterior urethritis, prostatitis, seminal vesiculitis) and then only by specially trained personnel in the dispensary or hospital. In cases of the acute condition local treatment may do more harm than good.

2. Local treatment (for females). (a) In the acute stage, external cleanliness only; no douches.

(b) For acute pelvic inflammatory disease rest in bed, application of ice bags to the abdomen, keeping the bowels open (if enemas are necessary, clean the perineum carefully before inserting the rectal tube, to avoid infecting the rectum) and hot cleansing douches.

3. Chemotherapy. (a) Even under ambulatory conditions, acute gonorrhea may be cured by appropriate measures in a large proportion of cases. Therefore, when considered desirable and local conditions permit, acute gonorrhea may be treated on an ambulatory basis in working quarantine (paragraph 7, AR 40-235, Oct. 11, 1939). Under such conditions hospitalization will be necessary for the treatment of complications.

(b) Sulfathiazole and sulfapyridine are better than sulfanilamide.

(c) In the doses to be advised, neither sulfathiazole nor sulfapyridine is likely to cause serious toxic manifestations.

(d) If sulfathiazole fails, use sulfapyridine (see following sections). If neither is available, use sulfanilamide.

(e) Other medication by mouth (such as copaiba, sandalwood oil or alkalis) is unnecessary and should not be used.

D. Determination of Cure (in Males).—The following procedure should be carried out, on the fourteenth to twentieth day after the start of treatment and if all symptoms have disappeared:

1. Before the patient voids, massage the prostate with sufficient vigor to obtain secretion.

2. Examine the secretion for pus and gonococci by the gram stain.

(f) *Treatment Scheme for Acute Gonorrhea**

		Plan A		
Day Plan (Inclusive)	Drug	Daily Dose, Gm.	Each Dose, Gm.	Daily Administration
1st	Sulfathiazole	3.0	0.5	Every 3 hr., 6 a. m. to 9 p. m.
2d to 4th	Sulfathiazole	2.0	0.5	Every 5 hr., 6 a. m. to 9 p. m.
5th	Examine patient. If discharge persists, stop sulfathiazole and switch to plan B. If symptoms have disappeared, continue plan A, as follows:			
5th to 9th	Sulfathiazole	2.0	0.5	Every 5 hr., 6 a. m. to 9 p. m.
10th	If patient remains symptom free, stop all treatment			
10th to 14th	None			
14th	Proceed with determination of cure (see D)			
		Plan B		
To be used for sulfathiazole-resistant patients on fifth day				
5th	Sulfapyridine	3.0	0.5	Every 3 hr., 6 a. m. to 9 p. m.
6th to 10th	Sulfapyridine	2.0	0.5	Every 5 hr., 6 a. m. to 9 p. m.
10th	Examine patient. If discharge persists, stop sulfapyridine, and if patient is not already in hospital transfer to hospital for special care			
	If symptoms have disappeared, continue plan B as follows:			
11th to 15th	Sulfapyridine	2.0	0.5	Every 5 hr., 6 a. m. to 9 p. m.
16th	If patient remains symptom free, stop all treatment			
16th to 20th	None			
20th	Proceed with determination of cure (see D)			

* Before treatment, a careful inquiry should be made as to previous treatment with sulfanilamide or its derivatives, special care being taken to exclude the possibility of self-administered chemotherapy. See also paragraph 12, Circular Letter No. 81, Dec. 5, 1940 (general comment on toxic effects).

3. If no gonococci are found, repeat this procedure weekly for eight weeks. If the result is negative for eight weeks, discharge the patient as cured. Supporting evidence of culture is desirable (see F).

4. If on any of these occasions the prostatic secretion contains gonococci on smear or culture, repeat plan A, using sulfapyridine instead of sulfathiazole (dosage identical), and in addition gently massage the prostate twice weekly.

5. The passage of instruments into the urethra and/or indulgence in alcohol or sexual excitement are not recommended as criteria of cure.

E. Determination of Cure (in Females).—1. Make a pelvic examination for masses or discharge.

2. Examine smears (gram stain) from the urethra once every two weeks for three months.

3. Confirm negative or positive results of urethral smear examinations by culture of material from the urethra and the cervix at monthly intervals on the last day of the menstrual period.

4. To obtain material for smear and culture, massage the urethra and Skene's glands. Use a bivalve specu-

lum to expose the cervix. Do not use a lubricant on the speculum. Cleanse the external os with dry cotton. Squeeze the cervix gently with the blades of the speculum. Remove material with a platinum loop or a cotton-wound applicator for smear. Use a cotton-wound applicator for removal of material for culture.

5. If no gonococci are found by smear or culture during three or four months of post-treatment observation, discharge the patient as cured.

6. If on any of these occasions gonococci are found by smear or culture, repeat plan A, using sulfapyridine instead of sulfathiazole.

F. Cultures in Determination of Cure.—Absolute proof of cure of gonorrhea demands a minimum of three consecutive negative cultures of prostatic secretion for men (at two week intervals) or of secretion from the cervix and the urethra for women (not oftener than at monthly intervals). If cultures are not available, determination of cure must depend on gram-stained smears.

G. Local Treatment for Sulfanilamide-Resistant Patients or Those with Complications Arising During Treatment (Posterior Urethritis, Prostatitis and so on).—When local treatment is necessary, it should be given at dispensaries or hospitals by specially trained personnel.

1. For sulfanilamide-resistant anterior urethritis: (a) Daily until discharge ceases, gently irrigate the anterior urethra with 1,000 cc. of warm 1:5,000 potassium permanganate solution by the gravity method, with the reservoir not more than 1 meter above the meatus. Do not distend the urethra.

(b) Daily until discharge ceases, inject not more than 8 cc. of 5 to 10 per cent mild protein silver solution into the anterior urethra (solution not more than one week old); retain for three minutes by having the patient compress the meatus with a thumb and a finger.

(c) All irrigations and instillations should be administered by a medical officer or a trained attendant, not by the patient.

2. For the active stage of posterior urethritis occurring as a complication of treatment: (a) Stop all local treatment until acute symptoms have subsided.

(b) Give hot hip baths for painful urination.

(c) Resume daily irrigations of the anterior urethra with potassium permanganate solution 1:5,000 when acute symptoms have subsided.

(d) After a week during which the first glass of urine has been nearly clear and the second glass entirely so, gently stroke the prostate before the patient voids. If this causes a persistent urethral discharge or results in symptoms of active posterior infection, do not repeat until the patient has been free from symptoms, the first glass of urine nearly clear and the second glass entirely so for one week.

(e) If the first massage does not cause any activation of signs or symptoms, repeat massage of the prostate twice a week and increase the pressure gradually until the pressure is fairly firm. Continue prostatic massage until the prostatic secretions become negative for gonococci.

(f) Make microscopic studies of prostatic secretion once a week for at least eight weeks. If all give negative results, discharge the patient as cured. (Cultures of prostatic secretions should be made if facilities are available.)

3. Posterior urethritis, epididymitis, acute prostatitis, acute seminal vesiculitis and acute arthritis arising as

complications of treatment require hospital care. If one of these complications is the original manifestation which brings the patient under medical observation, it will be frequently controlled by a day or two of ambulatory chemotherapy.

4. Chronic prostatitis, symptomless and manifested only by pus in the prostatic secretions, will, in general, be allowed to go untreated. Prolonged courses of prostatic massage are valueless.

H. *Serologic Follow-Up of Patients with Gonorrhea.*—As far as possible all patients, male and female, acquiring acute gonorrhea should have a serologic test for syphilis done on admission and at least one follow-up test in order to rule out symptomless infection with the latter disease. If only one such test is done, it should be performed three or four months after the onset of gonorrhea.

SYPHILIS

A. *General Principles of Treatment.*—1. No treatment is to be given for suspected early syphilis until the diagnosis is made either by dark field examination or by confirmed serologic tests. No therapeutic tests are to be used.

2. Begin with an arsenical for early and latent syphilis (one-half full dose initially followed by full doses) with a bismuth compound for late syphilis.

3. The preferred arsenical in and out of hospital is mapharsen (arsenoxide). When mapharsen is not available, neoarsphenamine may be used. The preferred bismuth preparation is bismuth subsalicylate. In the hospital under competent direction, arsphenamine or another arsenical may be employed.

4. Tryparsamide and fever therapy are not to be used outside a hospital.

5. The range of dosage of mapharsen is 30 to 60 mg. per intravenous injection, of neoarsphenamine 0.45 to 0.9 Gm., of arsphenamine 0.3 to 0.6 Gm., of bismuth subsalicylate 0.2 Gm. the average normal dose.

6. A course of arsenical treatment is eight weekly intravenous injections. A course of bismuth therapy is ten weekly intramuscular injections. A normal rest period, when allowed, is eight weeks.

7. Treatment is to be of the continuous alternating type, i. e. without rest periods between courses and with arsenical courses alternating with bismuth courses—not alternate injections or simultaneous injections of the two drugs except as indicated for overlap.

8. Each treatment is to be recorded on the syphilis register of the patient. If for any reason a syphilis register is not available, a written record is to be kept and transferred to the standard form as soon as possible.

9. Each entry will include date, drug, dose and reaction.

10. It cannot be too strongly emphasized that clock-like calendar regularity of the treatment schedule without long or short time variations or lapses is critically important to both the control and the cure of infection. It is most important in the first twelve months. Every effort must be made to impress this fact on enlisted men and officers as well as on medical personnel on all occasions.

11. Emphasis should also be placed on the completion by each patient of the full schedule of treatment in the time called for by the type of infection presented, discarding serologic tests as guides, so-called "abortive" procedures for seronegative primary syphilis or "treatment to noninfectiousness."

12. The infectiousness of syphilis is not to be predicated on the result of a blood test but is judged by the total time, course, laboratory tests, physical inspection and treatment summation of the case.

B. *Serologic Controls in Treatment.*—1. Patients with early syphilis (first two years of infection) are to have a serologic test of the blood:

- (a) At the start of treatment.
- (b) With the second treatment if the reaction is negative at the start.
- (c) At the sixteenth week (average positive reaction should become negative).
- (d) At the twenty-fourth week (positive reaction indicates need for spinal fluid examination).
- (e) At the beginning and end of each course of bismuth therapy thereafter.
- (f) Once in three months during two years of post-treatment probation.
- (g) Before discharge from service at any time.

2. Patients with early syphilis are to have a test of the spinal fluid:

- (a) Between the twenty-fourth and the fifty-second week in all cases.
- (b) If fluid is abnormal, repeat at least once in six months.
- (c) If weak or strong positive reactions appear in the blood after negative ones.

3. Early latent syphilis (first four years of the infection) is to be considered early syphilis in serologic controls as to both blood and spinal fluid.

4. Patients with latent syphilis (after fourth year of infection of uncertain duration) are to have a test of the blood once in three months whether on treatment or probationary observation. (Thirty per cent irreversible reactions are to be expected.)

5. Patients with latent syphilis are to have a test of the spinal fluid:

- (a) As soon after treatment is begun as practicable.
- (b) If after a series of negative reactions the reaction of the blood becomes positive.
- (c) Before discharge, if practicable, unless there has previously been a negative reaction.

C. *Control of Relapse and Infectiousness.*—1. Early syphilis is to be regarded as infectious until the second injection has been given and should be rated potentially infectious if treatment for any reason is irregular or inadequate (subschedule).

2. Physical inspection of the skin (including palms and soles), mucosae, anus and genitalia should be performed as often as circumstances permit during treatment and at each probationary inspection.

3. Patients should be warned to look for and report oral, cutaneous and genital lesions.

4. The involution of the chancre or secondary symptoms should be watched to detect treatment-resistant conditions.

5. Dark field examination is of great help in recognizing cutaneous, mucosal and genital relapse lesions. The blood test may give a negative reaction.

6. Relapsing or treatment-resistant infectious types of syphilis require special consideration with a view to effective therapy and quarantine control.

D. *Treatment Interpretation of Spinal Fluid Observations.*—1. Reports on the spinal fluid should include:

- (a) Quantitative complement fixation test.
- (b) Total protein or standard globulin test.
- (c) Differential cell count.
- (d) Colloidal test. The fluid should be bloodless.

2. Minimal abnormality. Slight increase in protein (Pandy, plus-minus to 1 plus) or a leukocyte count over 5. Continue with standard treatment; recheck at or before probation.

3. Grade I. Blood reaction positive or negative, spinal fluid Wassermann reaction negative, leukocyte count 10 to 25, protein 1 plus, colloidal gold curve low second zone (syphilitic). Patient recovers with continuance of standard treatment. Recheck in six months.

4. Grade II. Blood reaction positive or negative, usually positive, spinal fluid Wassermann reaction positive in low dilutions, negative in high dilutions, leukocyte count 5 to 100 plus, protein 2 plus, colloidal gold curve pronounced second zone (syphilitic). Patient recovers under prolongation and intensification of standard intravenous and intramuscular treatment.

5. Grade III. Blood reaction strongly positive; spinal fluid Wassermann reaction strongly positive with all dilutions; leukocyte count 7 to 100 plus; protein 3 plus; colloidal gold curve first zone (dementia paralytica). Patient will not recover without tryparsamide and/or fever therapy. Should be sent to the hospital as soon as practicable.

E. *Prevention of Reactions.*—1. A physical examination and a urinalysis should precede the institution of treatment.

2. Minimal medical inspection should be made before each treatment.

The neck and arms should be exposed. Inspect:

- The face for edema of eyelids and dermatitis.
- The open mouth for bleeding gums, petechiae.
- The scleras for jaundice.
- The elbow flexures and wrists for dermatitis, petechiae.
- Signs of intercurrent infection or fever. Any positive finding demands closer examination.

Questions: Patient sick after last treatment? Bowels loose? Urine dark? Skin itch? Any rash? Gums or nose bleed? Stool black? Pain in arm or hip? These questions may if practicable be posted in sight of the patients and pointed to by persons giving treatment.

3. Technical suggestions:

- Discard discolored drugs and solutions and damaged ampules.
- Shake and aerate mapharsen. Do not shake or aerate the other arsenicals.
- Inject mapharsen rapidly to avoid thrombosis (no danger of speed shock or nitritoid crisis). Other arsenicals should be injected *slowly* (speed shock, nitritoid crisis).
- Thoroughly shake oily suspensions.
- Aspirate on a syringe after insertion of the needle before injecting anything, especially intramuscularly.
- Inject intramuscularly into the inner angle of the upper outer quadrant of the buttock. Alternate.
- Massage long and firmly after withdrawing the needle from the buttock.
- Have the patient prolong the massage to three minutes.
- Rest should be ordered if practicable after administration of arsenicals; exercise after intramuscular injections.
- Warn the patient to report his reactions.
- Test the urine once in two to four weeks. Do not stop or modify treatment for slight albuminuria or cylindruria.
- Watch the mouth and the gums; use hydrogen peroxide or some other oxidant and an astringent. Dental attention should be given.

4. General antireaction therapy:

- Epinephrine hydrochloride solution 1:1,000 from 6 to 10 minims (0.36 to 60 cc.) subcutaneously for speed shock or nitritoid crisis.

(b) Dextrose 500 cc. of 5 per cent solution intravenously for jaundice or dermatitis.

(c) Venesection (400 cc.) for threatened cerebral accidents.

(d) Liver extract given intramuscularly is occasionally helpful for suspected damage to the liver.

(e) For cerebral vascular accidents, hypertonic saline solution intravenously 500 cc. (1.5 per cent).

(f) For blood dyscrasias, transfusions.

(g) The value of sodium thiosulfate for any type of treatment reaction is questionable.

5. Treatment is to be stopped and the patient hospitalized if any of the following symptoms appear:

(a) An itchy dermatitis of the face and flexures.

(b) Jaundice.

(c) Petechial or other hemorrhagic lesions.

(d) Evidence of cerebral injury, even though slight.

6. If treatment is stopped because of reaction, medical consultation as to further procedure should be had as promptly as possible, especially for patients with early syphilis.

F. *Cardiovascular, Visceral and Resistant (Grade 3) Neurosyphilis.*—Cardiovascular, visceral and symptomatic and asymptomatic neurosyphilis with grade III spinal fluid require special treatment in a hospital. For additional details see standard textbooks.

G. *Treatment of Precocious Late Syphilis (Tertiary).*—As soon as possible, patients with precocious late syphilis (early gummatous and rupial lesions and bone lesions following lapse after inadequate heavy metal coverage of arsenical treatment) should be hospitalized for combined fever and arsenical therapy.

H. *Treatment of Congenital Syphilis.*—On recognition or on appearance of active lesions, congenital syphilis should be treated on the schedule of early syphilis.

1. Diagnostic Nomenclature for Syphilis in the Army.—

Primary
Secondary early
Secondary relapsing
Latent

Tertiary:

Mucocutaneous	Visceral
Osseous	Other (specify)
Ocular	

Cardiovascular:

Aneurysm (saccular)	Aortitis, uncomplicated
Aortic regurgitation	

Neurosyphilis:

Asymptomatic	General paresis (dementia paralytica)
Acute syphilitic meningitis	Gumma
Diffuse meningovascular	Syphilis with psychosis (other than general paresis [dementia paralytica])
Tabes dorsalis	
Taboparesis (the tabetic form of dementia paralytica)	

Congenital

Type undetermined

Poisoning from arsphenamine (include all arsphenamines and mapharsen)

Specify nature, as

Jaundice	Hemorrhagic encephalitis
Dermatitis	Other (specify)
Blood dyscrasia	

Poisoning from trypanarsamide (specify nature):

Amblyopia
Dermatitis

Other (specify)

Poisoning from bismuth (specify manifestation)
Poisoning from mercury (specify manifestation)
Poisoning from iodides (specify manifestation)
Fever therapy for syphilis
Malaria inoculata Other (specify)
Mechanical fever
No disease, spinal puncture

The terms will be used as follows:

1. Primary. To include conditions presenting the primary lesion of syphilis (the chancre) which have not yet shown secondary manifestations. This diagnosis must be confirmed by dark field examination, a serologic test of the blood or both. If the serologic test of the blood is negative, the diagnosis of primary syphilis is not permissible without the demonstration of *Spirochaeta pallida* by dark field examination.

2. Secondary, early. To include only those examples of early syphilis which show one or more of the manifestations of systemic dissemination of the spirochete, for example, generalized enlargement of lymph glands, cutaneous eruption, mucous patches, condylomata lata, patchy alopecia, laryngitis, pains in the bones and febrile reaction. The chancre may or may not be present and, if present, may be in any stage of evolution. In early secondary syphilis the manifestations of systemic spirochetal dissemination are increasing, have attained their maximum or are waning. This diagnosis must be confirmed by dark field examination, a serologic test or both.

In cases of early secondary syphilis and in addition to the manifestations listed, ocular or neurologic complications (iritis, neuroretinitis, acute syphilitic meningitis) should be specially recorded as "Syphilis, secondary, early: Manifested by . . ."

3. Secondary, relapsing. In relapsing secondary syphilis a second systemic dissemination of the spirochete has taken place, usually because of premature cessation of arsenical therapy. The commonest time for relapse is within the first six months, and the majority of all early relapsing infections occur within the second year. In addition to the relapsing lesions of skin and mucous membrane which may be observed there may also occur other relapsing lesions, particularly in the eye and in the nervous system. These should be reported as "Syphilis, secondary, relapsing. Manifested by . . ."

4. Latent. Secondary symptoms have subsided, and the active manifestations of late syphilis have not yet supervened. There are no evidences of syphilis other than a positive serologic reaction of the blood. The condition will not be classified as latent unless asymptomatic neurosyphilis has been excluded by a negative result of examination of the spinal fluid. The date of such examination of the spinal fluid will be stated in all cases in which the disease is diagnosed as "latent," as follows: "Spinal fluid negative . . ." Cases in which there is no evidence of syphilis other than a positive serologic reaction of the blood and in which involvement of the central nervous system has not been excluded by examination of the spinal fluid are to be reported as instances of "Syphilis, type undetermined, spinal fluid not examined. Manifested by . . ."

5. Tertiary. This classification is to be used only in cases of active lesions of late syphilis other than involvement of the central nervous system and the cardiovascular system. The lesion may be a gumma or it may be a diffuse process. It may involve any

organ or tissue of the body. If the central nervous system or the cardiovascular system is involved, however, these cases will not be reported as instances of tertiary syphilis but, because of their gravity and frequency and the necessity for specialized treatment, will be reported as cases of neurosyphilis or of cardiovascular syphilis, as the case may be.

The majority of all examples of tertiary syphilis other than cardiovascular syphilis or neurosyphilis will fall within four categories: mucocutaneous (late syphilitic gummatous lesions of skin or mucous membranes); osseous (periostitis, osteomyelitis, arthritis, synovitis); ocular (iritis, uveitis, keratoiritis, keratitis, choroiditis, but not including optic atrophy), and visceral (hepatic, gastric).

In such cases special diagnoses should be made:

"Syphilis, tertiary, mucocuta- "Syphilis, tertiary, ocular"
neous "Syphilis, tertiary, visceral"
"Syphilis, tertiary, osseous"

If tertiary manifestations occur which do not fit into one of these categories, diagnose as:

"Syphilis, tertiary, other" (specify).

6. Cardiovascular. To include all lesions of the heart and great vessels.

(a) Aneurysm (saccular). Do not use for a fusiform dilatation of the aorta. Specify artery involved.

(b) Aortic regurgitation. Specify whether with or without cardiac decompensation.

(c) Aortitis, uncomplicated. To be used only for patients with symptoms and physical or roentgen signs of syphilitic aortic involvement in the absence of aneurysmal sacculation or aortic regurgitation.

7. Neurosyphilis. To include all syphilis with involvement of the central nervous system, classified further as follows:

(a) Asymptomatic. To be used only for patients with early or late syphilis who have no symptoms or detectable physical signs of involvement of the central nervous system and in whose cases the diagnosis is based on the routine finding of abnormalities in the spinal fluid.

(b) Acute syphilitic meningitis. This usually occurs within the first two years of the disease, most commonly as a relapse phenomenon (neurorecurrence), manifested by the usual signs of low grade meningeal involvement with or without cranial nerve palsies.

(c) Diffuse meningovascular. This is a catch basket category to include neurosyphilis which does not fit into other diagnostic categories enumerated. Manifestations to be stated in each instance.

(d) Tabes dorsalis. "Neurosyphilis, tabes dorsalis. Manifested by . . ."

(e) Taboparesis (the tabetic form of dementia paralytica). To be used only for patients with definite psychiatric signs of paresis complicated by definite clinically demonstrable evidence of damage to the posterior columns of the spinal cord.

(f) General paresis (dementia paralytica). To be limited to patients who show psychic changes in addition to neurologic signs and the characteristic changes in the spinal fluid. Patients with parietic (dementia paralytica) type spinal fluid but without psychic changes will be reported under "Syphilis, diffuse meningovascular. Manifested by . . .," or under some other type of neurosyphilis.

(g) Gumma. Include gumma of brain and spinal cord only. Gumma of other organs or tissues to be reported as "Syphilis, tertiary. Manifested by . . ."

(h) With psychosis. To include neurosyphilis with psychosis (other than that associated with paresis and taboparesis).

8. Congenital. To be used only when there is definite evidence of the existence or former existence of the

characteristic changes of congenital syphilis, such as interstitial keratitis, Hutchinson teeth, saber shins and other bone changes, saddle nose and eighth nerve deafness. The congenital origin of syphilis is not to be assumed merely because time and the circumstances of the infection cannot be ascertained and there is no scar of a primary lesion.

9. Type undetermined. To include conditions accurate diagnosis of which has not been made. Every effort should be made to make a complete examination and proper diagnostic classification in all cases.

The suggested terms for various drug poisonings are intelligible as they stand.

Fever therapy. It is particularly desirable to diagnose especially the conditions of patients treated with fever and to specify the type of fever employed.

The manifestations of the disease will be given in each case. The lesions will be located and briefly described. The results of laboratory procedures will be stated.

The diagnosis of syphilis shall not appear in the records of any person unless the presence of the disease has been established. For that reason patients for whom such a diagnosis has not been definitely made will not be recorded at any time as "Under observation for syphilis."

When syphilitic patients under treatment or during post-treatment observation are admitted to or retained in the hospital for follow-up examination (including spinal puncture) and when no new developments are found which justify a change or an addition to the original diagnosis as to syphilis, the diagnosis for that hospital admission or portion thereof due to observation for syphilis shall be recorded as syphilis, old, of the type in existence at the time of admission or retention in the hospital, unless all tests for syphilis give negative results and the patient can be pronounced cured, in which case the diagnosis shall be recorded as "Under observation (syphilis); no disease."

CHANCROIDAL INFECTION

A. *Definition*.—Chancroid is a venereal disease transmitted only by direct contact and characterized by single or multiple genital ulcers possessing irregular crater-like margins, usually with nonindurated base and a tendency toward the formation of complicating suppurating inguinal adenitis. The incubation period is usually three to fourteen days.

B. *Diagnosis*.—It is important to rule out the presence of mixed syphilitic and chancroidal infection. For this purpose all local medication should be withheld until three dark field examinations of material from accessible lesions, carried out on successive days, have given negative results. During this period saline solution dressings alone should be used. A serologic test of the blood for syphilis must be secured and the Frei test for lymphogranuloma venereum should be carried out if possible. Tests of the blood for syphilis should be made at monthly intervals for six months after healing of the chancroidal lesions. Laboratory tests for the absolute diagnosis of chancroid (Ito-Reenstierna cutaneous test or staining or culture isolation of the *Ducrey bacillus*) are not recommended.

C. *Treatment*.—Chemotherapy: (a) Local. Accessible lesions should be cleansed with soap and water and dried. They should then be completely covered with powdered sulfanilamide and a loose, dry dressing applied. This should be repeated at daily intervals until

the lesion heals. In patients with tight phimosis and underlying ulcerative lesions the phimotic preputial cavity should be irrigated twice daily with 1:5,000 potassium permanganate solution.

(b) Systemic. Administer sulfanilamide 3 Gm. daily for five days, utilizing divided doses at four hour intervals. For nine succeeding days administer sulfanilamide 2 Gm. daily, also in divided doses. At the end of fourteen days discontinue all chemotherapy.

Practically all chancroidal infections will respond to this routine. In fact, if the lesion does not heal, doubt is cast on the correctness of the diagnosis of chancroid and the patient should be restudied from the diagnostic standpoint and, if necessary, treated surgically.

(c) Surgical. Surgical procedures designed to relieve phimosis or paraphimosis should be resorted to only on the basis of sound clinical judgment.

(d) For chancroidal bubo. Most lesions of this type will subside with systemic sulfanilamide therapy. If extensive suppuration is already present or occurs, the bubo may be opened by a small incision, the pus aspirated and the cavity packed with sulfanilamide powder.

LYMPHOGRANULOMA VENEREUM

A. *Definition*.—This disease concept includes the conditions formerly known as lymphogranuloma inguinale, lymphopathia venerea, climatic bubo, esthiomene and inflammatory rectal stricture.

B. *Etiology*.—Condition caused by a filtrable virus, probably multiple strains.

C. *Geographic Distribution*.—Worldwide, most frequent in the tropics.

D. *Clinical Picture*.—A systemic disease of the lymphatic vessels and structures, usually originating in a trivial and transitory lesion of the penis, vulva, vagina or rectum, which frequently escapes the patient's notice.

The invasion of the lymphatic glands usually occurs from ten to thirty days after infection but occasionally is delayed for months. Inguinal adenitis is often bilateral and occasionally subsides without suppuration. During this stage constitutional symptoms may be observed. Lymph nodes may fuse to the skin, resulting in multiple areas of softening followed by numerous fistulas. Extensive scarring accompanies healing. The anorectal symptom is usually found in the female and is characterized by rectal pain, discharge of blood and pus from the anus, a tendency toward extreme chronicity and the production of rectal stricture.

E. *Diagnosis*.—Differentiate from malignant tumors, Hodgkin's disease, tularemia, tuberculosis, pyogenic infections, chancroidal bubo and syphilis.

F. *Specific Diagnosis (Frei Test)*.—In an infected person, intracutaneous injection of Frei antigen (0.1 cc.) gives rise to an inflammatory papule at least 0.5 cm. in diameter, often with peripheral erythema and sometimes with a central vesicle. The papule appears within forty-eight hours and persists for several days.

In infected persons the Frei test may give positive results for years. In suspected cases in which the test gives negative results, it should be repeated. Positive reactions occur in over 95 per cent of cases after the development of the bubo.

Mixed venereal infections should be ruled out by the dark field examination of material from genital lesions for the causative organism of syphilis. Frequent serologic examinations should be continued for at least six months after the disappearance of the lymphatic symptoms.

G. Treatment.—1. Local treatment: Patients with acute inguinal adenitis should be hospitalized whenever possible. The fluctuant nodes may be aspirated, but incision and drainage should be delayed until the effect of chemotherapy has been observed. Radical excision is inadvisable because of the risk of elephantiasis of the scrotum or of the vulva.

Patients with the acute anorectal syndrome should be treated in the same manner.

Patients with rectal stricture require hospital management.

2. Chemotherapy: The use of sulfanilamide and its derivatives in cases of lymphogranuloma venereum has not yet been established, but there are some clinical indications that they may be of considerable value. If used they should be employed as follows:

(a) Sulfanilamide. Sulfanilamide therapy should consist of the administration of 1.25 Gm. of the drug four times daily for the first four or five days, followed by a reduction to from 0.5 to 0.75 Gm. four times daily for an additional seven days. If inflammatory symptoms (not residual scarring) persist, repeat the chemotherapeutic course after a rest period of ten to fourteen days, utilizing the same agent or one of the allied chemotherapeutic agents.

(b) Sulfapyridine. Sulfapyridine should be administered in doses of 3 Gm. for the first day and 2 Gm. for the following ten to twelve days (in divided doses at four hour intervals). The course should be repeated after a rest period of ten to fourteen days if clinical evidence indicates active extension of the glandular process.

The acute anorectal syndrome should be treated in the same manner as the inguinal manifestations. Stricture or other late complications should receive special consideration.

3. Biologic treatment. Frei antigen given intravenously in 0.2 to 0.3 cc. amounts every second day may be of value. The duration of treatment will depend on the patient's response.

GRANULOMA INGUINALE

A. Definition.—Granuloma inguinale is a chronic disease due to infection with a Leishmania-like organism. It involves primarily skin and mucous membranes, rarely with coincident adenopathy; it is characterized by vivid-hued, shining, verrucous, vegetating nodules of granulating tissue with a hemorrhagic surface surrounded by a thin, easily excoriated epidermis. The condition spreads by peripheral extension and autoinfection, often involving the entire genital area. It may involve large adjacent areas of the lower part of the abdomen and the thighs. The lesions show little or no tendency to spontaneous healing and may persist for months or years.

B. Diagnosis.—The clinical appearance of a chronic process involving the groin and genital areas with little

involvement of the lymph nodes is characteristic of the disease. The finding of Donovan bodies by the Wright stain in deep tissue scrapings or in a biopsy specimen from a peripheral area of diseased tissue (including a section of normal adjacent skin) confirms the diagnosis.

Lymphogranuloma venereum, chancroidal infection and syphilis should be considered in the differential diagnosis, and the appropriate test for each condition should be performed.

C. Treatment.—Antimony and potassium tartrate may be administered intravenously in doses of 0.03 to 0.12 Gm. (beginning with 3 cc. and increasing to 12 cc. of a 1 per cent solution, if tolerated), three times a week, the maximum tolerated dose to be given for fifteen doses.

Fuadin 1 to 3 cc., 0.06-0.18 Gm., or anthiomaline 1 to 3 cc., or 0.06-0.18 Gm. (both of these are complex antimony compounds), may be given intramuscularly two to three times weekly for twenty to twenty-five doses when the patient has difficulty in taking antimony and potassium tartrate or when the lesions have not improved satisfactorily with that drug.

Courses of antimony and potassium tartrate, fuadin or anthiomaline should be continued for at least four months after all lesions are completely healed; otherwise relapse is almost certain to occur.

Local treatment of the lesions may be limited to daily dressings, or surgical excision of the entire area may be necessary. Large areas may be treated with solid carbon dioxide pencils.

ENCLOSURE TO CIRCULAR LETTER NO. 18

1. The following designations will be used in obtaining drugs recommended in Circular Letter No. 18:

- (a) Items 10800 to 10804—Arsphenamine U. S. P.
- (b) Items 13000 to 13005—Neosarsphenamine U. S. P.
- (c) Item 11063—Bismuth subsalicylate U. S. P., for intramuscular injection (1 cc. = 0.13 Gm. bismuth subsalicylate).
- (d) Item 14635—Sulfanilamide, powder.
- (e) Item 14637—Sulfanilamide, 5 grain tablets.
- (f) Item 14639—Sulfapyridine, 7.7 grain tablets.
- (g) Item 14641—Sulfathiazole, 7.7 grain tablets.
- (h) Item 14891—Tryparsamide U. S. P., 2 Gm. ampules.
- (i) NS-1—Arsenoxide (Mapharsen, Parke, Davis & Co.).
- (j) NS-1—Frei antigen (1 cc. vial—10 tests) Lederle.
- (k) NS-1—Antimony and potassium tartrate 1 per cent in 5 cc. ampules (each ampule contains 0.05 Gm.).
- (l) NS-1—Fuadin (Winthrop).
- (m) NS-1—Anthiomaline (Merck) 16 per cent solution, 1 cc. = 0.01 Gm. antimony (lithium antimony thiomalate).

2. All standard and nonstandard items will be obtained in accordance with existing regulations.

ADDITIONAL NURSES NEEDED FOR THE GOVERNMENT

An acute shortage of nurses for Civil Service positions related to the National Defense Program prevails, especially in some parts of the country, the U. S. Civil Service Commission announces. Further information concerning these positions may be had by writing to the U. S. Civil Service Commission, Washington, D. C., or by applying to the Secretary of the Board of U. S. Civil Service Examiners at any first or second class post office.

There has recently been an increased demand for nurses under the U. S. Public Health Service in extracantonment zones and where large defense industries are located. The U. S.

Civil Service Commission announces open continuous examinations to secure nurses. Two examinations are now open for receipt of applications. One, announcement 38, under the title of Public Health Nurse, \$2,000 a year, and Graduate Nurse, \$1,800 a year, is open for the U. S. Public Health Service and the Indian Service, including Alaska. Applicants are not given a written test but are rated on their professional training and experience. The other, announcement 100, under the title of Junior Graduate Nurse, \$1,620 a year, is for the U. S. Public Health Service, the Indian Service and the Veterans' Administration. This examination includes a written test now, but it is expected that it will be reannounced soon as an "unassembled" examination.

HOSPITAL DETACHMENTS TRANSFERRED TO AIR CORPS ASSIGNMENTS

The War Department has ordered the transfer of a number of Station Hospital Detachments in the Ninth Corps Area to Air Corps Facility assignments in the Northwest. The transfers are permanent and affect the following Medical Detachments: forty-seven enlisted men at Fort Lewis, Wash., set up for Felts Field, Wash., to be transferred in grade to the Air Corps Facility, Boise, Idaho, at the earliest practical date; forty-two enlisted men at Fort Lewis set up for Portland, Ore., to be transferred in grade to the Air Corps Facility, Portland, Ore.; sixty-two enlisted men at McChord Field, Wash., set up for Spokane, Wash., to be transferred in grade to the Air Corps Facility, Fort George Wright, Wash.; forty-one enlisted men at McChord Field set up for Bellingham, Wash., to be transferred in grade to the Air Corps Facility, Everett, Wash., about May 30; the enlisted men of the Medical Detachment, unassigned, at Fort Douglas, Utah, consisting of twenty-nine privates, will be transferred to the Air Corps Facility, Pendleton, Ore., about May 25.

TEMPORARY PROMOTIONS IN THE ARMY

The War Department has announced that promotions to the grade of general officer, temporary or permanent, are made solely on the basis of selection. Heretofore promotions to grades below that of general officer have been based on seniority or length of service. The War Department does not intend to seek a change at this time in the methods of making permanent promotions; it has reached a decision, however, that future temporary promotions of Regular Army officers to the grade of colonel will be determined on a basis of selection. The system may eventually lead to the extension of the policy of selection for temporary promotion to all grades and in all components during the present emergency.

Consideration is being given by the War Department to the best method of determining those to be promoted. Available for selection will be the lieutenant colonels and majors of the promotion list of the Regular Army. These officers comprise a large group, all of whom have had practically the same

length of service and the majority of whom have had World War experience.

In selecting those to be promoted, great weight will be given to character and leadership. The extensive maneuvers scheduled for this summer and fall will provide an unusual opportunity for officers to demonstrate qualities of leadership under field conditions. Physical and mental vigor will be essential qualities in determining selections for command duty. General efficiency and age will, of course, be considered.

Under existing law permanent promotions to the grade of lieutenant colonel from the rank of major occur on the completion of twenty-three years of service, provided a specified number of those years have been in the grade of major. There are many Regular Army majors with more than twenty-three years' service whose promotion has been delayed pending the completion of the required years of service in the grade of major. Since many lieutenant colonels of the Officers' Reserve Corps on active duty have reached that rank after but eighteen years of service, the limitation imposed on the Regular Army majors is to be canceled in the interest of fairness and efficiency.

A special policy with respect to medical officers and chaplains in field grades will be announced shortly.

Retired officers called to active duty will receive temporary promotions, if recommended by their commanding officers, on the following basis:

Lieutenant colonel to colonel on completion of twenty-eight years of active service.

Major to lieutenant colonel on completion of twenty-three years of active service.

Captain to major on completion of twelve years of active service.

First lieutenant to captain on completion of three years of active service.

Second lieutenant to first lieutenant on completion of one year of active service.

Retired officers of the Medical Corps and chaplains will be advanced, to the next grade, if so recommended, on the completion of twenty-six years of service for the grade of colonel, and varying from twenty to three years of service for the lower grades. Officers securing initial temporary promotions under this policy will not be advanced more than one grade prior to at least a year's additional active duty.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY THIRD CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Third Corps Area, which comprises the states of Pennsylvania, Virginia, District of Columbia and Maryland:

ALBERT, Arnold, Captain, Washington, D. C., Camp Lee, Va.
ARONSON, Joseph David, Major, Wayne, Pa., Fort Belvoir, Va.
BACHMANN, Lawrence Charles, 1st Lieut., Pittsburgh, Camp Lee, Va.
BERNSTEIN, Joseph, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.

BONE, Charles Alfred, Jr., 1st Lieut., Glenside, Pa., Fort Eustis, Va.
BOYSEN, Theophilus Henry, 1st Lieut., Philadelphia, Camp Davis, N. C.
BUTLER, Raymond Kenneth, Captain, Madison, Va., Camp Davis, N. C.
CAPRIOTTI, Octavius Anthony, 1st Lieut., Hatfield, Pa., Fort George G. Meade, Md.

CARABELLO, Natal Christopher, 1st Lieut., Reading, Pa., Fort George G. Meade, Md.

CHESLER, William, 1st Lieut., Philadelphia, Fort George G. Meade, Md.
CUBBERLEY, Charles Lamb, Jr., 1st Lieut., Philadelphia, Camp Davis, N. C.

FINN, Joseph Lawrence, Captain, Philadelphia, Fort George G. Meade, Md.

FLEGGLER, Saul Milton, 1st Lieut., New Kensington, Pa., Camp Davis, N. C.

FLEMING, William Herbert, 1st Lieut., Shelocta, Indiana County, Pa., Camp Lee, Va.

FOSTER, John Van Valzah, 1st Lieut., Harrisburg, Pa., Fort Eustis, Va.

GLADSTONE, Joseph Edward, 1st Lieut., Exmore, Va., Camp Lee, Va.

GLASS, Albert Julius, 1st Lieut., Fort George G. Meade, Md.

GLAUDEL, Stanley Francis, 1st Lieut., Fort George G. Meade, Md.

GRAHAM, Richard Walter, Jr., 1st Lieut., Duxbury, Mass., Fort George G. Meade, Md.

HORVAT, Arthur Joseph, 1st Lieut., Uniontown, Pa., Carlisle Barracks, Pa.

HUBBARD, Charles Crow, 1st Lieut., Uniontown, Pa., Carlisle Barracks, Pa.

JONES, Clement Russell, Jr., Captain, Dixmont, Pa., Fort Eustis, Va.

JONES, Lawrence Paul, Captain, Emporia, Va., Camp Pendleton, Va.
KIMMEL, Henry Arden, 1st Lieut., Lewistown, Pa., Fort Belvoir, Va.
KRAJESKI, Romuald John Francis, 1st Lieut., Wilkes-Barre, Pa., Fort Eustis, Va.

LAURENT, August Aloysius, 1st Lieut., Avella, Pa., Camp Lee, Va.
LAWSON, Edward Kirby, Jr., 1st Lieut., Penbrook-Harrisburg, Pa., Camp Lee, Va.

LINHART, William Oran, Jr., 1st Lieut., Jeanette, Pa., Fort Eustis, Va.

MAFFUCCI, Victor, Jr., 1st Lieut., Everett, Pa., Camp Lee, Va.

McCAFFERTY, John Sidney, 1st Lieut., Freeport, Pa., Indiantown Gap Military Reservation, Pa.

McCLAIN, Clifton Andrew, Jr., 1st Lieut., Christiana, Pa., Fort George G. Meade, Md.

McFARLAND, Paul Edwards, 1st Lieut., Saxonburg, Pa., Camp Davis, N. C.

McLENAHAN, Thomas Morrow, Jr., 1st Lieut., Pittsburgh, Camp Lee, Va.

MILLER, Cledith Aten, 1st Lieut., Wilkes-Barre, Pa., Camp Lee, Va.

MILLER, Harry Archer, Captain, Baltimore, Fort Monro, Va.

MILLER, Ira Clyde, Captain, Camp Hill, Pa., Fort George G. Meade, Md.

MITCHELL, Edward Albert, 1st Lieut., Clinchco, Va., Carlisle Barracks, Pa.

MITCHELL, John Adams, 1st Lieut., Monaca, Pa., Fort George G. Meade, Md.

MOBILIO, Joseph Anthony, 1st Lieut., Philadelphia, Camp Davis, N. C.

MOSELEY, Vince, 1st Lieut., Philadelphia, Fort Belvoir, Va.

MYERS, William, 1st Lieut., Pittsburgh, Camp Pendleton, Va.

NEILL, John Leitch McVicker, 1st Lieut., Smethport, Pa., Fort Eustis, Va.

NICASTRO, Gennaro Carlo, 1st Lieut., Philadelphia, Fort George G. Meade, Md.

PACKER, Bernard Donald, 1st Lieut., Richmond, Va., Fort Belvoir, Va.

PAYNE, Wilmer Howard, 1st Lieut., Charlottesville, Va., Fort Bragg, N. C.

PARKER, Henry Stoddert, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.

PATRICK, Nicholas Emil, 1st Lieut., Scranton, Pa., Fort Eustis, Va.

PEERY, James McGuire, 1st Lieut., North Tazewell, Va., Fort George G. Meade, Md.
PIERCE, Leslie Staebler, 1st Lieut., Greensburg, Pa., Fort Eustis, Va.
ROTHERMEL, John Keim, 1st Lieut., Strausstown, Berks County, Pa., Camp Lee, Va.
SCHENTHAL, Joseph Edwin, 1st Lieut., Baltimore, Fort George G. Meade, Md.
SCHLAN, Louis, 1st Lieut., Lewisburg, Pa., Camp Davis, N. C.
SEAWELL, William Asa, 1st Lieut., Raven, Va., Fort George G. Meade, Md.
SOBEHL, Harry, 1st Lieut., Philadelphia, Fort George G. Meade, Md.

FIFTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Fifth Corps Area, which comprises the state of Ohio, West Virginia, Indiana and Kentucky:

BEHM, Alton W., 1st Lieut., Chardon, Ohio, Fort Benjamin Harrison, Ind.
BERNDT, Albert L., 1st Lieut., Portsmouth, Ohio, Fort Knox, Ky.
BROWN, David, 1st Lieut., Columbus, Ohio, Fort Benjamin Harrison, Ind.
BROWN, John Edwin, Jr., 1st Lieut., Columbus, Ohio, Fort Hayes, Ohio.
CHRENKA, Paul, 1st Lieut., Cleveland, Fort Thomas, Ky.
CUNNINGHAM, Ralph B., 1st Lieut., Cincinnati, Fort Knox, Ky.
DEL VECCHIO, James J., 1st Lieut., Rayland, Ohio, Fort Knox, Ky.
DONLEY, Robert F., 1st Lieut., Columbus, Ohio, Fort Hayes, Ohio.
GARRETT, Evan L., 1st Lieut., Murray, Ky., Fort Hayes, Ohio.
GOLD CAMP, John S., 1st Lieut., Youngstown, Ohio, Fort Benjamin Harrison, Ind.
GROSSMAN, Royal G., Lieut. Col., Lakewood, Ohio, Fort Knox, Ky.
GROVE, Paul D., 1st Lieut., Cincinnati, Fort Knox, Ky.
HARTZLER, Adrian J., 1st Lieut., Wooster, Ohio, Fort Knox, Ky.
HARVEY, Archelaus D., 1st Lieut., Lebanon, Ohio, Fort Hayes, Ohio.

SEVENTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Seventh Corps Area, comprising North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming:

ALFTINE, David Carl, 1st Lieut., Vinton, Iowa, Corps Area Service Command Reception Center, Fort Snelling, Minn.
ALLEE, William Sylvanus, 1st Lieut., St. Louis, Corps Area Service Command Replacement Center Infirmary, Fort Leonard Wood, Mo.
DOUGLAS, Paul Lowell, 1st Lieut., Columbia, Mo., 92d Engineers, Fort Leonard Wood, Mo.
FRITSCH, Carl John, 1st Lieut., New Ulm, Minn., Corps Area Service Command Replacement Center Infirmary, Fort Riley, Kan.
HARRIS, Donald Macrae, 1st Lieut., Manchester, Iowa, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo.
HOFFMAN, Richard Frederick, 1st Lieut., Warren, Ark., 214th General Hospital, Camp J. T. Robinson, Ark.
LEIGHTON, Robert Sisson, 1st Lieut., Evansville, Minn., Corps Area Service Command Station Hospital, Fort F. E. Warren, Wyo.
LYNCH, Harry Orange, Captain, Little Rock, Ark., Corps Area Service Command Induction Station, Fort Snelling, Minn.
MEYER, Wallace Martin, 1st Lieut., Rollingstone, Minn., 30th Field Artillery, Camp Roberts, Calif.
NEEL, Harry Bryan, 1st Lieut., Albert Lea, Minn., Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo.
NEU, Harold Nicholas, 1st Lieut., Sac City, Iowa, Corps Area Service Command Induction Station, Fort Snelling, Minn.

EIGHTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Eighth Corps Area, which comprises the states of Colorado, Arizona, New Mexico, Oklahoma and Texas:

BIGLER, Ivan Edward, 1st Lieut., Ada, Okla., Lou Foote Flying Service, Stamford, Texas.
BUELL, Arthur Louis, 1st Lieut., Vancouver, B. C., 55th Medical Battalion, Fort Sam Houston, Texas.
CHRISTMAN, Edmund Eugene, 1st Lieut., Pueblo, Colo., Station Hospital, Fort Bliss, Texas.
COLLINS, William Arthur, Jr., 1st Lieut., El Paso, Texas, Second Division, Fort Sam Houston, Texas.
DAVIS, Robert Louis, 1st Lieut., Holbrook, Ariz., 112th Cavalry Medical Detachment, Fort Clark, Texas.
DRYDEN, Sam Hefner, 1st Lieut., Abilene, Texas, 55th Medical Battalion, Fort Sam Houston, Texas.
DUFF, Kenneth Robert, 1st Lieut., Kansas City, Mo., 55th Medical Battalion, Fort Sam Houston, Texas.
EPPS, Curtis Howard, 1st Lieut., Duncan, Okla., Station Hospital, Fort Sill, Okla.
GILL, Earl K., Captain, Corpus Christi, Texas, Station Hospital, Camp Hulen, Texas.
HAMPTON, Dan E., 1st Lieut., Denver, 55th Medical Battalion, Fort Sam Houston, Texas.
HARGIS, William Huard, Jr., 1st Lieut., San Antonio, Texas, Station Hospital, Fort Sam Houston, Texas.

SOMERS, Lewis Frank, 1st Lieut., Lynchburg, Va., Fort George G. Meade, Md.
STILL, Joseph William, 1st Lieut., Greenbelt, Md., Camp Davis, N. C.
STRONG, Paul Stone, 1st Lieut., Baltimore, Fort Eustis, Va.
THOMPSON, Joseph Lawn, Jr., 1st Lieut., Washington, D. C., Indian-town Gap Military Reservation, Pa.
WELSH, John William, 1st Lieut., Leechburg, Pa., Camp Davis, N. C.
WIDDOWSON, William Work, 1st Lieut., Indiana, Pa., General Dispensary, U. S. Army, Philadelphia.
YOUNG, Frederick Frick, 1st Lieut., Easton, Pa., Fort George G. Meade, Md.

HELD, George A., Captain, Jasper, Ind., Fort Knox, Ky.
HULSE, Charles A., 1st Lieut., Cleveland, Fort Thomas, Ky.
MAPLE, John L., 1st Lieut., Louisville, Ohio, Fort Knox, Ky.
MELTZER, Harold Jack, 1st Lieut., Cleveland, Fort Benjamin Harrison, Ind.
MOORE, Randolph P., 1st Lieut., Cleveland, Fort Thomas, Ky.
MOORE, William A., 1st Lieut., Cincinnati, Fort Benjamin Harrison, Ind.
OSMOND, John D., Jr., 1st Lieut., Cleveland Heights, Ohio, Fort Knox, Ky.
PALM, John M., 1st Lieut., Brazil, Ind., Fort Knox, Ky.
PARK, James H., 1st Lieut., Ashtabula, Ohio, Fort Benjamin Harrison, Ind.
PIMSNER, Arthur A., 1st Lieut., Lakewood, Ohio, Fort Thomas, Ky.
SCHILLINGER, Arnold A., 1st Lieut., Chillicothe, Ohio, Fort Knox, Ky.
SELIGMAN, Bert, 1st Lieut., Toledo, Ohio, Fort Benjamin Harrison, Ind.
SHILLING, Harry E., 1st Lieut., Troy, Ohio, Fort Knox, Ky.
SIEGEL, William B., 1st Lieut., Alum Creek, W. Va., Fort Knox, Ky.
VANDE VELDE, Joseph D., 1st Lieut., Cleveland, Fort Knox, Ky.
WASILKO, Joseph J., 1st Lieut., Youngstown, Ohio, Fort Knox, Ky.
WHERLEY, Harold F., 1st Lieut., Coshocton, Ohio, Fort Hayes, Ohio.
WILLIAMS, Robert E., 1st Lieut., Barborton, Ohio, Fort Knox, Ky.
YORK, Dillard B., Jr., 1st Lieut., Columbus, Ohio, Fort Hayes, Ohio.

PETERSON, Donald Herbert, 1st Lieut., St. Paul, Corps Area Service Command Induction Station, Fort Des Moines, Iowa.
PUMPHREY, Loira Cromwell, Major, Keokuk, Iowa, Command and General Staff School, Fort Leavenworth, Kan.
RAE, Harold Burton, 1st Lieut., Torrington, Wyo., Corps Area Service Command Station Hospital, Fort F. E. Warren, Wyo.
SACH-ROWITZ, Alvan, Major, Moose Lake, Minn., 40th Field Artillery, Camp Roberts, Calif.
SENN, Emmett Jacob, 1st Lieut., Herculaneum, Mo., Corps Area Service Command Replacement Center Infirmary, Fort Riley, Kan.
SMILEY, Edward Archibald, 1st Lieut., Junction City, Kan., Corps Area Service Command Replacement Center Infirmary, Fort Riley, Kan.
SMITH, James Omer, 1st Lieut., Clinton, Mo., Corps Area Service Command Induction Station, Fort Leavenworth, Kan.
SPIRY, Arthur William, 1st Lieut., Mobridge, S. D., 217th General Hospital, Fort Riley, Kan.
STREET, Bernard, 1st Lieut., St. Cloud, Minn., Corps Area Service Command Induction Station, Fort Des Moines, Iowa.
SUBBY, Walter, 1st Lieut., Hibbing, Minn., Corps Area Service Command Reception Center, Fort Snelling, Minn.
SULLIVAN, Paul John, 1st Lieut., Rushville, Neb., 85th Field Artillery, Camp Roberts, Calif.
WATSON, William John, 1st Lieut., Holdingford, Minn., Corps Area Service Command Replacement Center Infirmary, Fort Riley, Kan.
WILKE, Frank Albert, 1st Lieut., Woodward, Iowa, Corps Area Service Command Replacement Center Infirmary, Fort Riley, Kan.
WOLF, William Kenneth, 1st Lieut., Hay Springs, Neb., Corps Area Service Command Reception Center Infirmary, Fort Des Moines, Iowa.

HICKS, Yale, 1st Lieut., San Antonio, Texas, Station Hospital, Fort Sam Houston, Texas.
LED BETTER, William Harry, 1st Lieut., Wichita Falls, Texas, 55th Medical Battalion, Fort Sam Houston, Texas.
MATTS, Robert Marshall, Captain, Yuma, Ariz., 25th Infantry, Fort Huachuca, Ariz.
NICHOLSON, William D., 1st Lieut., Houston, Texas, Ellington Field, Texas.
PAUL, Thomas G., 1st Lieut., Syracuse, N. Y., 104th Infantry Battalion (Army Transport), Fort Sam Houston, Texas.
PAVLETICH, Louis Martin, 1st Lieut., Raton, N. M., 55th Medical Battalion, Fort Sam Houston, Texas.
REDING, Anthony C., 1st Lieut., Tulsa, Okla., 202d Coast Artillery, Fort Bliss, Texas.
ROGERS, Albert Mitchell, 1st Lieut., San Antonio, Texas, 55th Medical Battalion, Fort Sam Houston, Texas.
SALMON, George Wilbur, 1st Lieut., St. Louis, 55th Medical Battalion, Fort Sam Houston, Texas.
SELLERS, Fred William, 1st Lieut., Dallas, Texas, Ellington Field, Texas.
SMITH, William Carleton, 1st Lieut., Houston, Texas, 55th Medical Battalion, Fort Sam Houston, Texas.
WHITE, Toler R., Major, Kingman, Ariz., S. S. Service System, Santa Fe, N. M.
WILSON, Francis W., 1st Lieut., San Antonio, Texas, 55th Medical Battalion, Fort Sam Houston, Texas.
WOLFE, Alfred S., 1st Lieut., Houston, Texas, Ellington Field, Texas.
YEARY, Edwin Curtis, 1st Lieut., St. Paul, 55th Medical Battalion, Fort Sam Houston, Texas.

ORGANIZATION SECTION

OFFICIAL NOTES

THEODORE G. KLUMPP APPOINTED DIRECTOR DIVISION OF FOODS, DRUGS AND PHYSICAL THER- APY OF AMERICAN MEDI- CAL ASSOCIATION

Following the untimely death of Dr. Paul Nicholas Leech, who had served for many years as Secretary of the Council on Pharmacy and Chemistry, Director of the Chemical Laboratory and Director of the Division of Foods, Drugs and Physical Therapy of the American Medical Association, the Board of Trustees gave careful consideration to the problem of securing a successor. The importance of this position in relationship to the demands made on its incumbent for judicial decisions, leadership and the assumption of responsibility are so great that but few of the many persons considered seemed to fill the requirements. Now the Board of Trustees announces the appointment to this position of Dr. Theodore G. Klumpp, at present chief of the Drug Division of the Food and Drug Administration of the United States Government.

Dr. Klumpp graduated with the degree of bachelor of science from Princeton University in 1924, magna cum laude; in 1928 he received the degree of doctor of medicine from Harvard Medical School; in 1939 he was made a fellow of the American College of Physicians. Following graduation in medicine he did research and investigative work in the Children's Hospital in Boston for one year. He served as intern in the Peter Bent Brigham Hospital for one year and as assistant resident physician in Lakeside Hospital, Cleveland, from 1930 to 1932. Then he accepted the appointment as instructor in internal medicine at Yale University Medical School, associate physician in the New Haven Hospital, chief of the Hematology Clinic and director of the Medical Laboratories in the New Haven Hospital, holding these positions from 1933 to 1936. At the same

time he was associate examiner of the National Board of Medical Examiners and secretary of Yale Medical Society. From 1936 to 1937 he was assistant clinical professor of internal medicine in Yale University. At this time also he accepted the appointment as medical officer of the Food and Drug Administration in the United States Department of Agriculture, becoming chief medical officer and then chief of the Drug Division in the Food and Drug Administration, which is now a part of the Federal Security Administration.

In recent years Dr. Klumpp has kept in touch with medical science by serving as adjunct clinical professor of medicine in George Washington University School of Medicine and attending physician in the Gallinger Municipal Hospital of Washington, D. C. He holds membership in many important organizations, including the American Society for Clinical Investigation, the American Association for the Advancement of Science, the American College of Physicians and Sigma Xi. The bibliography of his writings begins in 1928 and includes more than twenty-five contributions on various aspects of research and administration in public health.

Dr. Klumpp will assume his position with the American Medical Association on July 1.

RADIO BROADCASTS

The last two programs to be broadcast in the series "Doctors at Work" are:

May 28. The Doctor as a Citizen.
June 4. A. M. A. Convention.

The program is scheduled over the Blue network of the National Broadcasting Company Wednesday at 10:30 p. m. eastern daylight saving (9:30 eastern standard) time (9:30 Chicago daylight saving, 8:30 central standard, 7:30 mountain standard, 6:30 Pacific standard time).

MEDICAL LEGISLATION

STATE MEDICAL LEGISLATION Florida

Bills Introduced.—S. 343 and Committee Substitute for H. 274 propose to require every physician, midwife or other person in attendance at the birth of a child to instil or have instilled in the eyes of the baby within one hour after birth a 1 per cent fresh solution of silver nitrate or other effective prophylactic approved by the state board of health. S. 416 and H. 923, to amend the osteopathic practice act, propose, among other things, to require licensed osteopaths to renew their licenses annually and at that time to pay a renewal fee of \$5 to the osteopathic board. After Jan. 1, 1942 the right of a licentiate to a renewal of his license will be conditioned also on his attendance in the preceding year at the two days educational program as promulgated and conducted by the state osteopathic association. S. 497 and H. 1030 propose a method by which all counties of the state may establish and maintain public hospitals and levy a special tax and issue bonds for the construction and maintenance of such hospitals. Whenever one hundred or more resident freeholders of any county petition the board of county commissioners to do so, the commissioners shall submit the question of establishing and operating a hospital and levying a special tax therefore to the qualified electors of the county. H. 916 proposes to enact a separate massage practice act and to create an independent board of massage to examine and license applicants for licenses to practice massage. The bill states "That

the practice of massage is hereby declared a profession, and for the purpose of this Act is hereby defined as follows, viz.: The scientific manual manipulation of the tissue and muscle of the human body, together with the skilful use of scientific apparatus usually associated with the practice of massage in administering such treatments as cabinet baths, turkish baths, reducing treatments, fomentations, natural and artificial heliotherapy, vibratory treatments and colonic-irrigations." H. 978, to amend the state Food, Drug and Cosmetic Act, proposes, among other things, that a drug shall be deemed to be misbranded if it contains any quantity of the following drugs or any quantity of their derivatives and preparations: "aminopyrine, barbituric acid, cinchophen, dinitrophenol, sulfanilamide, carbromal (Bromdiethyl-acetyl-carbamide), chloral, chloral hydrate, chlorbutanol, paraldehyde, sulfonal (Sulfonmethane), tetrional (Diethyl-sulfon-diethyl-methane) or trional (sulfon-ethylmethane); unless it is sold on a written prescription signed by a member of the medical, dental or veterinary profession who is licensed by law to administer such drug, and its label bears the name and place of business of the seller, and serial number and date of such prescription, and the name of such member of the medical, dental or veterinary profession." H. 1012 proposes to make it unlawful for any person except a licensed wholesale druggist, a registered pharmacist or a licensed physician to sell or distribute any amytal, luminal, veronal, barbital, acid diethylbarbituric or any of its salts, derivatives or compounds of the foregoing substances. The persons

who are authorized to sell or distribute these drugs must record the name and address of the purchaser, the amount sold and the date of sale. The bill also proposes to create a state board of drug examiners to be composed of the members of the board of pharmacy, the state chemist and the director of the state college of pharmacy, which is to be empowered to determine from time to time such additional drugs as are dangerous and poisonous and is to be vested with the power to place the additional drugs "under the restriction as herein set forth." H. 1023 proposes to condition the issue of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate that the party is not epileptic, insane or feeble-minded, is free of pulmonary tuberculosis in a communicable stage, and a smear and specimen of blood from the party has been submitted to the Florida State Board of Health, which has advised the physician that the party is free from any communicable venereal disease. H. 1046 proposes to authorize the Board of County Commissioners of Leon County to assess a special tax annually, not to exceed 3 mills on the dollar on all real and personal property taxable, to create a fund for the medical and hospital treatment of the poor of the county.

Massachusetts

Bill Introduced.—H. 2445, which reported on H. 869, proposes that if any physician is informed that a patient has been involved in an accident and that the injuries subject to treatment are the results of the accident the physician, if he has been employed by or has rendered services to any insurance company within one year next prior to the first treatment of the injuries, shall inform the patient in writing to that effect and shall furnish him with the names of the insurance companies in question.

Nebraska

Bill Introduced.—Bill 513 proposes that a license to practice osteopathy shall confer on the holder "the right to practice osteopathy in all its branches, including operative surgery with instruments, as taught in the osteopathic colleges recognized by the American Osteopathic Association."

South Carolina

Bill Introduced.—H. 817 proposes that hereafter all domestic servants who present themselves for employment shall furnish their employer with a certificate from a practicing physician or from a public health officer that they have been examined within two weeks prior to the time of the presentation of the certificate and that they are free from all contagious, infectious and communicable diseases. The certificate also must show "the nonexistence of any venereal disease which might be transmitted." The bill proposes that all domestic servants must

be examined at least once a year and must present to the employer following the examination a certificate similar to the one just referred to.

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 2475 and S. 860 have been reported to the Senate, without amendment, with recommendation that they pass. The former proposes to prohibit prostitution within such reasonable distance of military or naval establishments as the Secretaries of War or Navy shall determine to be needful to the efficiency, health and welfare of the Army and Navy. The latter, in addition to providing for the suppression of vice in the vicinity of military camps and naval establishments, also proscribes the sale of alcoholic liquors at or within any military camp, station, fort, post, yard, base, cantonment, training or mobilization place which is used at the time for military purposes.

Bills Introduced.—S. 1485, introduced by Senator Bailey, North Carolina, proposes to amend the sections of the Social Security Act relating to aid to the blind by providing, among other things, that the term "aid to the blind" shall include the furnishing of rehabilitation and other services to the blind and the furnishing of services for the restoration and conservation of vision. S. 1504, introduced by Senator Langer, North Dakota, proposes to amend the Selective Training and Service Act of 1940 by providing for the deferment of students until the end of the academic year during which they are selected for training and service. H. R. 4688, introduced by Representative Marcantonio, New York, proposes a nationwide system of social security. This bill, among other things, provides for an annual expenditure of not less than \$400,000,000 for the construction of hospitals, health centers, clinics, laboratories and other institutional facilities and a similar amount for public health services, including maternal and child health services, prevention and control of disease, dental care and other related medical and health services. H. R. 4737, introduced by Representative Voorhis, California, proposes to authorize the Administrator of Veterans' Affairs to issue regulations providing for more liberal policies in determining the service connection of disabilities of veterans. H. R. 4755, introduced by Representative Randolph, West Virginia, proposes to amend the act relating to the operation of stands in federal buildings by blind persons. The term "blind person" is redefined to mean a person having not more than 20/200 of visual acuity in the better eye with correcting lenses; or visual acuity greater than 20/200 but with a limitation in the fields of vision such that the widest diameter of the visual field subtends an angle no greater than twenty degrees.

WOMAN'S AUXILIARY

Arkansas

Dr. Preston Hunt, president, State Medical Association of Texas, recently addressed the auxiliary to the Bowie and Miller County Medical Society on "How the Auxiliary Serves the Medical Association."

Dr. Thomas P. Faltz, speaker at a meeting of the auxiliary to the Sebastian County Medical Society, February 10, outlined plans for a Negro hospital and explained how the auxiliary may assist the medical society in furnishing the hospital.

Florida

The meeting of the auxiliary to the Duval County Medical Society, January 9, at the home of Mrs. Gordon H. Ira, Jacksonville, was addressed by Dr. William H. McCullagh on "The Psychosis of Hitler."

Iowa

The organization committee, under the leadership of Mrs. W. R. Hornaday, announced the formation of an auxiliary in Hardin County. Officers of the new auxiliary are Mrs. Grace Potter Miller of Ackley, president; Mrs. R. R. Gaard of Radcliffe, vice president; Mrs. F. W. Haulihan of Ackley, secretary, and Mrs. J. W. Caldwell of Steamboat Rock, treasurer.

Oklahoma

At the February meeting of the Le Flore County auxiliary held at the home of Mrs. R. W. Minor in Spiro, Mrs. Earl Woodson read a paper on "Feeding the Army." Mrs. J. J. Hardy told of some scientific discoveries in 1940.

The Oklahoma County auxiliary met at the Y. W. C. A. in Oklahoma City in February. A first aid unit was organized among the members. Thirty members brought garments for the layette shower sponsored by the auxiliary and the other members donated money toward the layettes.

At the February meeting of the Pittsburg County auxiliary, which was held at the home of Mrs. Walter J. Dell, members sewed on layettes for the Red Cross.

West Virginia

The auxiliary to the Cabell County Medical Society met in January at the home of Mrs. C. P. S. Ford in Huntington. Prof. Walter Dove, of Marshall College, Huntington, spoke on his travels in Peru. Mrs. J. L. Hutchinson addressed the group on "Strange Bathing Customs in Different Countries." In February at a tea at the home of Mrs. Oscar Biern, plans were made to help with a carnival to aid Britain. The annual Doctor's Day Luncheon was held March 10.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Clinical Conference.—A clinical conference was held in San Bernardino, April 1, for the medical societies of San Bernardino, Riverside and Orange counties. Dr. Carl F. Rusche discussed "Blood in the Urine: Origin and Procedure in Diagnosis"; Dr. Isaac Y. Olch, "Tumors and Inflammation of the Breast," and Dr. Alfred E. Gallant conducted a fracture clinic with special reference to femur and long bone fractures. All are of Los Angeles.

Medicolegal Dinner.—The fifth annual joint dinner of the Alameda County Medical Association and the Alameda County Bar Association was held at the Hotel Oakland, Oakland, April 15. Several past presidents of the state medical association were present and also judges of the appellate, superior and justice courts. Dr. Clarence A. DePuy, Oakland, a past president of the county medical association, was chairman of the committee for physicians, and Mr. Edwin Heafey, a past president of the county bar association, chairman of the committee for the lawyers. Entertainment included ten acts of vaudeville.

Refresher Courses.—Postgraduate work will be given in a series of refresher courses at the University of California Medical School, San Francisco, in June. The program will include courses by the division of medicine in the fields of heart disease, diseases of the blood and of the gastrointestinal tract and endocrine disturbances. The division of surgery will offer courses having to do largely with traumatic surgery, including a fracture course and the treatment of infections and hand injuries. The division of obstetrics and gynecology will summarize the most recent advances in the care of childbirth and the diseases of women.

CONNECTICUT

Warren Prize Awarded to Yale Faculty Members.—The Warren Prize for 1940 has been awarded to Drs. Hebbel E. Hoff and Louis H. Nahum, associate professor of physiology and research associate in physiology, respectively, Yale University School of Medicine, New Haven, for a paper on the mechanism of the electrocardiograph. The award of \$500 is presented "for the best dissertation, considered worthy of a premium, on some subject in physiology, surgery, or pathological anatomy." It was established in 1870 as the Warren Triennial Prize by Dr. J. Mason Warren in memory of his father, Dr. John C. Warren, the eminent Boston surgeon, who died in 1856. Dr. Warren's will provided that the accumulated interest of the fund shall be awarded every three years. Dr. Hoff graduated at Harvard Medical School, Boston, in 1936 and Dr. Nahum at Yale in 1916. This is the first time the Warren prize has been awarded in Connecticut.

DISTRICT OF COLUMBIA

Twenty-Five Year Teachers Honored.—The General Alumni Association of George Washington University honored nineteen teachers who have served twenty-five years or more on the faculty of the university at a luncheon at the National Press Club, April 5. Dr. Robert H. Harmon, president of the alumni association, presided, and Henry Grattan Doyle, A.M., dean of Columbian College, the senior college of the university, delivered an address on "Wholehearted Inter-Americanism." Included in the group honored were the following members of the medical school staff:

- Dr. Daniel L. Borden, associate professor of surgery.
- Dr. Cline N. Chipman, associate in anesthesia.
- Dr. Coursen B. Conklin, clinical professor of medicine.
- Dr. Harry H. Donnelly, professor of pediatrics.
- Dr. Frank A. Hornaday, assistant professor of medicine.
- Dr. Howard F. Kane, professor of obstetrics and gynecology.
- Dr. Harry H. Kerr, clinical professor of surgery.
- Dr. William B. Marbury, clinical professor of surgery.
- Richard K. Thompson, D.D.S., associate in dental surgery.
- Dr. Elijah W. Titus, clinical professor of obstetrics and gynecology.
- Dr. Charles Stanley White, professor of surgery.

ILLINOIS

Postgraduate Course in Venereal Disease.—The state department of health, cooperating with the U. S. Public Health Service and the Chicago Department of Health, conducted a postgraduate course in venereal diseases at the Municipal Social Hygiene Clinic, 27 East Twenty-Sixth Street, Chicago, April 14-May 3. Class sessions covered practical work in the diagnosis, reporting, treatment and clinical management of the venereal diseases as well as nutritional studies, laboratory demonstrations and methods of educating patients. Three weekly courses were included in the period with no charge to physicians licensed in Illinois.

Benevolent Fund for Physicians and Their Widows.—Through action of the council of the Illinois State Medical Society at its 1940 annual session a benevolent fund has been created for indigent physicians and their widows. Members of the committee on medical benevolence, created by the council, are Drs. John S. Nagel, Chicago, chairman; Charles H. Hulick, Shelbyville, and Clarence H. Boswell, Rockford. It was decided to allocate \$1 each year from dues of each member to the fund and to accept gratuities, endowments and the like for this end. Donations from the woman's auxiliary of the state society, raised through their various activities, will also be used for the benevolent fund. It was agreed that monthly benefits not to exceed from \$25 to \$30 would be appropriated for any case found, on investigation, to be worthy of aid.

Chicago

Loyola Alumni Clinics.—A series of clinics has been arranged by the members of the faculty of Loyola University School of Medicine for alumni, June 9-10. The series covers the specialties in medicine and will be conducted at Mercy Hospital.

Survey of Noise Measurement.—Plans have been announced for a noise measurement survey of Chicago and suburbs, according to a release from the Chicago Noise Reduction Council, May 2. Results of the survey will be classified into the sources of preventable noises in and about the city and will form the basis of the recently formed council's program of cooperative effort to reduce or eliminate preventable and unnecessary noises. Residents of Chicago and its suburbs are being asked to fill out a questionnaire listing noise nuisances in an attempt by the council to determine what noises are most annoying to people who live and work in this area. The following sources of noise appear on the questionnaire: automobile horns; loud speakers in homes and outside stores; trucks, busses (noisy mechanism or tires), automobile exhaust (or cutouts), noisy brakes on automobiles, riveting, pneumatic drills on streets and excavations, airplanes, noisy parties, locomotive whistles and bells, boat whistles, elevated trains, street cars, ash and garbage collection, newsboys' cries, traffic whistles, fire department sirens and trucks, milkmen, factories and offices. The Chicago Noise Reduction Council announces that application has been made to the secretary of state for a nonprofit organization charter.

Dean Cutter to Retire from Northwestern.—Dr. Irving Cutter will retire as dean of Northwestern University Medical School as of September 1, having reached the retirement age. He will continue his association with the medical school as dean emeritus and professor emeritus of medicine. He will also continue as health editor of the Chicago Tribune and superintendent of Passavant Memorial Hospital. He will be succeeded as dean by Dr. James R. Miller, associate professor of medicine and for eight years assistant to Dr. Cutter. Born in Keene, N. H., in 1875, Dr. Cutter graduated at the University of Nebraska College of Medicine, Omaha, in 1910. Jefferson Medical College, Philadelphia, conferred the degree of doctor of laws on him in 1931. He served as instructor in physiologic chemistry at Nebraska from 1910 to 1913; professor of biochemistry and director of the laboratory, 1913 to 1915, and as dean of the medical school from 1915 to 1925, when he became associate professor of medicine and dean at Northwestern. He has been medical director of Passavant since 1928. He has served as editor of the *Nebraska State Medical Journal*, a member of the editorial board of *Annals of Medical History* and as health editor of the *Tribune* since 1935. He was a captain in the medical corps of the U. S. Army, 1917-1918, and a lieutenant colonel in the medical section of the Officers Reserve Corps, 1920-1929. Dr. Miller was born in Murray, Utah, in 1905. He graduated at Northwestern University Medical School in 1930, becoming a member of the staff in 1934.

INDIANA

Medical Society Approves Smoke Abatement Work.—The Allen County Medical Society approved a resolution to support the smoke abatement campaign now in progress in Fort Wayne, newspapers reported, April 16. A committee named to aid in the smoke abatement program includes Drs. Karl C. Eberly, Eugene L. Bulson, William F. Gessler, Ernest R. Carlo, Harry V. Scott, Arthur N. Ferguson and Harvey L. Murdock.

Society News.—A symposium on the menopause will constitute the program of the Indianapolis Medical Society, May 27, with Drs. Isadore J. Kwitny, David A. Boyd Jr. and Maurice V. Kahler as the speakers. A quiz program on roentgenology was to be presented before a joint meeting of the Indianapolis and Seventh District medical societies, May 20. —Dr. George K. Fenn, Chicago, discussed "Peripheral Vascular Disease" before the Jasper-Newton and the Iroquois county medical societies in Kentland, April 22. —Dr. Edward C. Rosenow, Rochester, Minn., presented a report on poliomyelitis in the Fort Wayne area during the 1940 epidemic at a meeting of the Fort Wayne Medical Society, April 22. —Dr. Harry E. Mock, Chicago, discussed surgical and traumatic injuries before the Tippecanoe County Medical Society in Lafayette, May 13.

MARYLAND

The Thayer Lectures.—Dr. Joseph T. Wearn, professor of medicine, Western Reserve University School of Medicine, Cleveland, presented two addresses under the William Sydney Thayer and Susan Read Thayer Lectureship in Clinical Medicine at Johns Hopkins University School of Medicine, Baltimore, recently. His lectures were entitled "Observations on the Morphology and Functions of Some of the Components of the Coronary Circuit" and "Alterations in the Heart Accompanying Growth and Hypertrophy."

Physician Honored.—The Maryland Academy of Medical and Surgical Sciences devoted its meeting in Baltimore, March 18, to honoring Dr. Arthur G. Barrett, the society's president for the past twenty-two years. He was presented with a silver coffee service. The academy was founded in 1908 as a professional club for doctors of West Baltimore. In 1918, when Dr. Barrett was first elected president, the academy's name was changed to the West Baltimore Medical Society. In 1930, after its membership had been expanded to include other sections of the state, the name was again changed to the Maryland Academy of Medical and Surgical Sciences. At the recent meeting Dr. Barrett was elected president for the twenty-third time.

MASSACHUSETTS

District Meetings.—The Suffolk District Medical Society held its annual meeting at the Boston Medical Library, April 30. Dr. Robert M. Green presented a "Short History of Eclampsia" and Drs. Burton E. Hamilton, Arthur T. Hertig, Maurice B. Strauss, George van S. Smith, Duncan E. Reid, George C. Prather and Raymond S. Titus conducted a symposium on preeclamptic toxemia and eclampsia. —Dr. Harold G. Giddings, Boston, delivered the annual oration before the Middlesex South District Medical Society at its annual session in Cambridge, May 14; he discussed "Middlesex South and Massachusetts Medicine." —The Hampden District Medical Society was addressed at its annual meeting in Springfield, April 29, by Dr. Harold Edward MacMahon, Boston, on "Clinical and Morphologic Findings in Bright's Disease." —The Worcester North District Medical Society was addressed at its eighty-second annual meeting in Fitchburg, April 23, by Drs. Thomas J. Anglem, Boston, on "Treatment of General Peritonitis"; John W. Strider, Boston, "Carcinoma of the Lung"; Edwin T. Wyman, Boston, "Recent Advances in Infant Feeding and Therapy," and Joseph W. O'Connor, Worcester, "Indications for Cesarean Section."

MINNESOTA

The Lyon Memorial Lectures.—Dr. Ernst Gellhorn, professor of physiology, University of Illinois College of Medicine, Chicago, delivered the second annual Elias Potter Lyon Memorial Lectures in the Physiological Sciences at the University of Minnesota Medical School, Minneapolis, May 1-2. His subjects were "The Neurophysiological Basis of Some General Adjustment Reactions" and "Investigations on the Central Excitation of the Autonomic Nervous System and Their Significance for the Problem of Schizophrenia."

Community Welfare Planning.—A plan has been announced in Minneapolis whereby representatives of various organizations will serve as volunteers to improve local welfare services. The project is aimed to increase coordination of the services of one hundred and thirty public and private welfare organizations in Minneapolis through a program of research and planning. The *Bulletin* of the Hennepin County Medical Society states that three divisions are being formed, each supervised by an executive committee of five persons under the direction of a volunteer chairman and embracing three major divisions of social service, covering case work and relief, health and medical care and group work and recreation. Dr. Edgar J. Huenekens and Mr. James H. Baker, executive secretary, have been named to represent the Hennepin County Medical Society in the division on health and medical care.

NEBRASKA

State Tuberculosis Meeting.—The annual meeting of the Nebraska Tuberculosis Association was held in Kearney, May 23. At a medical session Dr. Lewis J. Moorman, Oklahoma City, was the guest speaker in a discussion on treatment. Other speakers were Drs. John F. Allen, Omaha, on "Fundamentals of the Tuberculosis Problem"; Ronald W. Thompson, Kearney, "Symptomatology of Tuberculosis as Correlated with Laboratory Findings"; Leland C. Albertson, Kearney, "Collapse Therapy"; Joseph A. Weinberg, Omaha, "Thoracoplasty" and Mrs. Florence Zulaut, field worker for the state tuberculosis hospital, Kearney, on follow-up work. Dr. Moorman and Dr. Arthur L. Miller, state health director, Lincoln, were the speakers at the annual banquet.

District Meetings.—Dr. Wallace E. Herrell, Rochester, Minn., was the guest speaker at a joint meeting of the Ninth and Tenth Councilor Districts of the Nebraska State Medical Association in Holdrege, April 10. His subject was "Chemotherapy of the Sulfonamide Groups." —Speakers at a meeting of the sixth councilor district in Osceola, April 14, were Drs. Charles W. McLaughlin Jr., Omaha, on "Recent Advances in Nutrition of Surgical Patients" and Frank Lowell Dunn, Omaha, "Modern Undernutrition." —The Third Councilor District met recently in Falls City, with the following speakers, among others: Drs. John F. Gardiner, Omaha, on "The Role of the Adrenal Glands in Health and Disease"; Charles L. Husted, Falls City, "Reduction of Fractures" and Arthur L. Miller, Lincoln, state director of health, "The Work of the State Department of Health." Dr. Roy H. Whitham, Lincoln, director of the state program of the National Youth Administration, gave a discussion of that project.

NEW JERSEY

Society News.—A symposium on anesthesia was presented at a meeting of the Hudson County Medical Society, Jersey City, May 6, by Drs. Alexander W. T. Povalski, John J. Muccia, William J. Gleeson and Abram P. Blakey, Jersey City, and John J. O'Shea, Weehawken. —Thomas F. Anderson, Ph.D., of the R. C. A. laboratories, Camden, addressed the Camden County Medical Society, Camden, May 6, on "The Electron Microscope as It Will Relate to Medicine." —Dr. Irving S. Wright, New York, addressed the section on medicine and pediatrics of the Academy of Medicine of Northern New Jersey, May 13, on "A Critical Evaluation of the Diagnosis and Treatment of Peripheral Vascular Diseases."

NEW YORK

State Medical Election.—Dr. George W. Cottis, Jamestown, was named president-elect of the Medical Society of the State of New York at the annual meeting in Buffalo, April 28 to May 1. Dr. Samuel J. Kopetzky, New York, was installed as president. Other officers elected were Drs. William A. Krieger, Poughkeepsie, second vice president, and Dr. Peter Irving, New York, secretary, reelected.

Tuberculosis in Industry.—The Trudeau School of Tuberculosis will sponsor a symposium on tuberculosis in industry, June 9-14, at the Saranac Laboratory for the Study of Tuberculosis, Saranac Lake. Subjects of the sessions will be the disease tuberculosis; incidence of tuberculosis in industrial groups; predisposing factors theoretically significant; incidence and causation of tuberculosis in various industries; methods of control. Among the speakers will be Drs. Leroy U. Gardner, Saranac Lake; Leslie L. Lumsden, U. S. Public Health Service; Elston L. Belknap, Milwaukee; Joseph A. Johnston, Detroit; Adolph G. Kammer, East Chicago, Ind.; Alton S. Pope, Boston; Anna M. Baetjer, Sc.D., Baltimore, and Louis I. Dublin, Ph.D., New York.

New York City

The Herter Lectures.—Michael Heidelberger, Ph.D., associate professor of biochemistry, College of Physicians and Surgeons, Columbia University, delivered the Christian A. Herter Lectures at New York University College of Medicine, April 22 and 23. The lectures were on "Immunochemistry."

Cancer Symposium.—Mount Sinai Hospital and the New York City Cancer Committee sponsored a cancer symposium, April 25, with the following speakers, among others: Drs. Samuel H. Geist on "Silent Carcinoma of the Cervix Complicating Incomplete Abortion"; Rudolph Kramer, "Resection of Larynx and Upper Esophagus for Postcricoid Carcinoma"; Paul Klemperer, "Relationship of Polypi to Carcinoma of the Colon"; Abraham Hyman, "Nephrectomy for Carcinoma of the Kidney with Removal of Tumor Thrombus from the Inferior Vena Cava," and Israel S. Wechsler, "Abdominal Syndrome as First Manifestation of Tumor of the Brain."

City to Build Cancer Hospital.—Announcement was made recently by Mayor La Guardia that the city will build a hospital for cancer patients as a cooperative project of the department of hospitals and Columbia University College of Physicians and Surgeons. The new institution, which the mayor has named the Nightingale Hospital, will cost about \$2,650,000 and will take the place of the old Cancer Institute on Welfare Island and the cancer clinic at 129 East Fifty-Ninth Street. Both the old buildings will be demolished. The new building will have a capacity of three hundred and fifteen beds, with about 20 per cent of the space devoted to research laboratories. It will be staffed jointly by the city and the medical school. Construction and maintenance costs will be borne by the city. It is expected that the hospital will be ready for service late in 1942 or early in 1943.

OREGON

Society News.—Dr. Kendall Emerson, New York, recently addressed a special meeting of the Multnomah County Medical Society, Portland, on "The Chemotherapeutic Approach to Tuberculosis." Dr. John H. Stokes, Philadelphia, addressed another special meeting, April 10, on syphilis.

State Board Election.—Dr. Frank E. Fowler, Astoria, was elected president of the state board of medical examiners at its April meeting, succeeding Dr. Irvin R. Fox, Eugene. Dr. Linford S. Besson, Portland, was reelected secretary-treasurer.

PENNSYLVANIA

Society News.—Dr. Floyd H. Bragdon, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, May 1, on "Treatment of Head and Back Injuries."—Dr. Walter E. Dandy, Baltimore, addressed the Cambria County Medical Society, Johnstown, May 8, on "Diagnosis and Treatment of Brain Tumors."—Dr. Edward S. Stafford, Baltimore, addressed the Dauphin County Medical Society, Harrisburg, May 6, on appendicitis.—Dr. Charles R. Austrian, Baltimore, addressed the Harrisburg Academy of Medicine, May 20, on "Diagnosis and Treatment of Some Chronic Diseases of the Lungs."—Philadelphia physicians presented the program of the Washington County Medical Society, Washington, May 14, as follows: Drs. Donald M. Pillsbury, "Superficial Pyogenic and Fungus Infections of the Skin and Their Treatment"; Kendall A. Elsom, "Treatment of Idiopathic Ulcerative Colitis"; Lewis Kraefer Ferguson, "Modern Methods in Office Surgery," and Louis H. Twyeffort, "Emotional Factors in the Etiology and Treatment of Medical Conditions."

Philadelphia

First McCrae Award.—Drs. Robert F. Norris and Alexander Rush received the first annual Thomas McCrae Award of \$100, which is to be granted annually to younger members of the medical staff of the Pennsylvania Hospital. The award, which honored Drs. Norris and Rush for the best publication of work done during 1940, was made at a special meeting April 22 at which Dr. Henry A. Christian, Hersey professor of the theory and practice of physic, emeritus, Harvard Medical School, Boston, made an address on "Scholarship in Medicine." The award was established in memory of the late Dr. Thomas McCrae, professor of practice of medicine and clinical medicine at Jefferson Medical College and chief of one of the medical services at the Pennsylvania Hospital. The subject of the prize winning paper was "A Comparison of the Prothrombin Levels of Maternal and Cord Blood at Delivery." Dr. Rush is now doing postgraduate work in Chicago.

Pittsburgh

Annual Mellon Lecture.—Dr. Carl V. Weller, professor of pathology, University of Michigan Medical School, Ann Arbor, delivered the twenty-fourth annual Mellon Lecture sponsored by the Society for Biological Research of the University of Pittsburgh, May 8. Dr. Weller's subject was "The Inheritance of Retinoblastoma and Its Relationship to Practical Eugenics."

Society News.—Speakers before the Allegheny County Medical Society, April 15, were Drs. Wilton H. Robinson on "Sense and Nonsense in the Treatment of Fractures"; Melvin Knoepp, "Recent Improvement in Pneumonia Mortality in Hospital Treatment"; John N. Frederick, "The Physician's Role in the Production of Neuroses," and Rutherford H. Ferguson, "An Evaluation of X-Ray Findings in Gallbladder Diagnosis."—Dr. Charles Anderson Aldrich, Winnetka, Ill., addressed the Pittsburgh Pediatric Society, April 18, on "Ancient Processes in the Scientific Age—Feeding Aspects."—Dr. Alfred W. Adson, Rochester, Minn., addressed the Pittsburgh Otological Society, April 23, on "Treatment of Cerebrospinal Rhinorrhea by Plastic Closure of the Craniosinus Fistula."

RHODE ISLAND

Society News.—Dr. Philip D. Wilson, New York, addressed the Providence Medical Association, April 7, on "Medical and Surgical Work in Great Britain." Dr. Frank B. Cutts and Donald B. Lindsley, Ph.D., Providence, addressed the association, May 5, on "Diagnosis of Cardiac Infarction with Particular Reference to the Precordial Electrocardiogram" and "The Electroencephalogram and Its Clinical Application" respectively.—George L. Salisbury, D.V.M., Wickford, was recently elected president of the Rhode Island Public Health Association.

Bradley Home Ten Years Old.—The Emma Pendleton Bradley Home, East Providence, celebrated the tenth anniversary of its opening to patients, April 8. The hospital held open house to the public and in the evening presented a medical program with Drs. Earl D. Bond, professor of psychiatry, University of Pennsylvania School of Medicine, Philadelphia, and Rustin McIntosh, Carpenter professor of pediatrics, Columbia University College of Physicians and Surgeons, New York, as the speakers. The Bradley Home is devoted to study and treatment of children with neurologic and behavior disorders. Approximately 600 patients have been treated in the ten years. In addition, the hospital has maintained a postgraduate training program for physicians and nurses and a program of scientific research. It was founded with an endowment left by the late Mr. and Mrs. George E. Bradley, Providence.

HAWAII

Plague.—Rats proved positive for plague have been found in Hawaii Territory as follows: 1 rat on February 4 and another on February 5, both at Kalopa Homesteads, Paaulu area, Hamakua District, Island of Hawaii; 1 rat on February 11 and another on February 18, both found about 8½ miles from Kahului, Island of Maui.

Postgraduate Lectures.—Dr. Marion A. Blankenhorn, Gordon and Helen Hughes Taylor professor of medicine, University of Cincinnati College of Medicine, Cincinnati, gave a course of postgraduate lectures on internal medicine before the Honolulu County Medical Society late in April and early in May. His subjects included pneumonia, nutrition, hypertension, gastroenteric bleeding and medical shock. He was also to be the guest speaker at the annual meeting of the Hawaii Territorial Medical Association May 2-4.

PUERTO RICO

Society News.—Dr. Ramon M. Suarez, San Juan, addressed the Humaçao District Medical Society at a meeting at the Fajardo District Charity Hospital, Fajardo, recently, on "Coronary Artery Disease in Puerto Rico." Dr. Guillermo Acosta, Fajardo, was elected president.—Dr. Jose Noya-Benitez, San Juan, was recently elected president of the San Juan District Medical Society, and Dr. Federico Hernandez Morales, San Juan, secretary.

Personal.—Drs. Charles Walter Clarke and Edward L. Keyes, New York, recently spent two weeks in Puerto Rico participating in a congress on venereal diseases held by the department of public health of the School of Tropical Medicine of the University of Puerto Rico, San Juan, in cooperation with the insular department of health.—Drs. Clifford

W. Wells, San Jose, Costa Rica, and Porter J. Crawford, Havana, Cuba, both of the Rockefeller Foundation staff, recently spent several days on the island visiting the health department and medical institutions.

GENERAL

Psychologic Literature of Aviation.—At the request of the Civil Aeronautics Authority, a systematic classification of the psychologic literature of aviation is being prepared by the WPA psychologic index project. The work, which includes 10,000 references totaling about 120,000 words, is intended for use by the physicians, officers, psychologists and technicians of the U. S. Army, Navy and Air Corps. It has been proposed that the WPA project follow up this study by selecting, abstracting, indexing and publishing current literature on the subject beginning with the middle of 1939, thus maintaining a complete up to date abstracting and indexing service on the psychology of aviation.

Surgeons Announce Memorial to Dr. Horsley.—The Southern Society of Clinical Surgeons has voted to establish a memorial to the late Dr. John S. Horsley Jr., Richmond, Va., a charter member of the society, who was killed in an automobile accident in November 1940, the first member to die in the organization's fifteen years' existence. A bronze tablet will be erected in St. Elizabeth's Hospital, Richmond. The action was taken during the society's recent annual session in Richmond. Dr. Charles B. Morton II, Charlottesville, Va., was elected president of the society at this meeting, succeeding Dr. James S. Speed, Memphis. Other officers include Drs. Malcolm D. Thompson, Louisville, Ky., vice president, and William P. Nicolson Jr., Atlanta, secretary-treasurer. The 1942 meeting will be in St. Louis.

Committee Seeks Psychiatrists.—The National Committee for Mental Hygiene wishes to get in touch with physicians who have had some psychiatric service and might be available during the emergency to help keep up the work of some mental hospital. The committee's request continues: "Some may be doing things which they consider not especially important; some may have retired. Obviously a person whose physical health makes him incapable of good service would not be available, but age of itself will not be considered very detrimental when medical staffs are short. It is requested that all those who see this notice inform the National Committee (1790 Broadway, New York City) of the name and address of any such physician. Many such men have not been actively engaged in psychiatry of late and hence are not members of psychiatric organizations, but their mental hospital experience in former years may have been of very good standard."

Society for Investigative Dermatology.—The fourth annual meeting of the Society for Investigative Dermatology will be held June 3 at the Hotel Allerton, Cleveland, under the presidency of Dr. Jesse Bedford Shelmire, Dallas, Texas. The program will include the following speakers:

- Dr. Shelmire, Study of Sensitivity to Poison Ivy.
- Dr. Morris H. Goodman, Baltimore, The Artificial Blister in the Study of Eosinophils with Particular Reference to Dermatitis Herpetiformis.
- Drs. Hamilton Montgomery, Rochester, Minn., and Morris Waisman, Chicago, Arsenical Epitheliomas.
- Drs. Frank E. Cormia and William W. Bryan, Montreal, Individual Action and Summation Effects of X-Ray and Commonly Used Dermologic Preparations on the Skin of the Albino Rabbit.
- Dr. Louis Schwartz, Bethesda, Md., Dermatitis from Synthetic Resin in Fabric Finishes.
- Drs. Adolph Rostenberg Jr. and Naomi M. Kanof, Washington, D. C., Studies in Experimental Sensitization of the Eczema-like Type in Humans.

American Human Serum Association.—The annual meeting of the American Human Serum Association will be held at the College Club, Cleveland, June 2-3, under the presidency of Dr. Stuart Mudd, Philadelphia. The meeting will be devoted to a symposium on blood substitutes and blood transfusion, with twenty-nine papers listed and others to be presented in abstract if time permits. Among the presentations will be:

- Morton F. Mason, Ph.D., and Dr. Alfred Blalock, Nashville, Tenn., The Use of Heat and Cold in Prevention and Treatment of Shock.
- Edwin J. Cohn, Ph.D., Cambridge, Mass., Properties and Functions of the Purified Proteins of Animal and Human Plasma.
- Drs. Sidney C. Madden, and George H. Whipple, Rochester, N. Y., Shock—Plasma Protein Building in Emergencies as Influenced by Intravenous Digests.
- Comdr. Charles S. Stephenson and Comdr. Lloyd R. Newhouser, M. C., U. S. Navy, Washington, D. C., and Dr. Edward H. Cushing, Cleveland, The Present Status of Blood Substitutes for the Navy.
- Drs. Max M. Strumia and John J. McGraw Jr., Bryn Mawr, Pa., Comparative Studies on Methods of Preservation of Plasma.
- Earl W. Florsdorf, Ph.D., Lansdowne, Pa., and Dr. Stuart Mudd, Philadelphia, Large Scale Desiccation of Blood Substitutes from the Frozen State: A Comparison of Currently Available Types of Equipment.
- Drs. Charles H. Best and Donald Y. Solandt, Toronto, Ont., Preparation of Concentrated and Dried Blood Serum as a War Project.
- Dr. Charles R. Drew, Washington, D. C., Blood Plasma for England.

Save Hospital Rubber Goods.—A release from the James M. Jackson Memorial Hospital, Miami, Fla., makes an appeal for the conservation of used hospital rubber goods in the interest of national defense. The release includes suggestions recently made by Mr. Harvey S. Firestone Jr. in a radio broadcast last fall:

It would be my suggestion that you sell your hospital's scrap rubber, including that from sheeting, hot water bottles, rubber gloves, tubing, etc., to any scrap dealer who will give you the best price for it. In that way it will find a route to the reclaiming plants, and the hospital will obtain some salvage value from it. Market prices of scrap rubber fluctuate the same as do prices of any other commodities. Further, different prices for the same grades will prevail in different communities because of differences in shipping costs that must be incurred to get the rubber to points where it can be reclaimed. Speaking generally, however, the types of scrap rubber which a hospital can accumulate will vary in price from less than a cent a pound to several cents per pound, with gloves and other "pure gum" articles commanding the higher prices. If the scrap is sorted by articles or grades of rubber, it should bring more than if sold in one bulk lot.

American Rheumatism Association.—The eighth annual meeting of the American Rheumatism Association will be held at the Hotel Cleveland in Cleveland, June 2. The speakers will be:

- Drs. Sidney Rothbard, Daniel Murray Angevine and Russell L. Cecil, New York, Influence of Gold Sodium Thiomalate (Mycocrystin) on Prevention of Hemolytic Streptococcus Arthritis in Rats.
- Dr. Albert B. Sahin and Joel Warren, Cincinnati, Curative Effect of Gold Salts in Experimental Chronic Arthritis in Mice with Reference to the Properties of Calcium Aurothiomalate.
- Dr. Richard H. Freyberg, Walter D. Block, Ph.D., and Oliver H. Buchanan, M.S., Ann Arbor, Mich., A Study of Gold Metabolism and the Fate of Gold Injected in the Treatment of Arthritis.
- Dr. Edward F. Hartung, New York, Bacteriostatic Action of Serum of Rheumatoid Arthritis Treated with Gold Salts.
- Drs. Currier McEwen, Ernst W. Bergmann and Harry Most, New York, Cytological Study of Synovial Biopsies in Various Types of Arthritis.
- Dr. John Staige Davis Jr., New York, The Liver, An Etiologic and Therapeutic Factor in Certain Types of Blood Disease and in Gout and Gouty Arthritis.
- Dr. George J. Baer, Boston, Fractures in Arthritis.
- Dr. William K. Ishmael, Oklahoma City, Use of Stilbene Derivatives in Treatment of Climacteric Arthralgia.

Association for Research in Ophthalmology.—The twelfth scientific meeting of the Association for Research in Ophthalmology will be held in Cleveland at the Hotel Cleveland, June 3, with the following speakers:

- Dr. John G. Bellows, Chicago, Studies in Capsular Permeability and Lens Swelling.
- Drs. Jonas S. Friedenwald and Wilhelm H. Buschke, Baltimore, Relation of Adrenalin to the Secretion of the Intraocular Fluid.
- Dr. Placidus J. Leinfelder, Iowa City, Multiple Extraocular Muscle Transplants in Monkeys.
- Dr. M. Joseph Mandelbaum and Esther U. Mintz, Ph.D., New York, Spectral Sensitivities of the Color Receptors as Measured by Dark Adaptation.
- Dr. Peter C. Kronfeld, Chicago, The Protein Content of the Aqueous Humor in Man.
- Samuel A. Talbot, M.A., and Wade H. Marshall, Ph.D., Baltimore, Physiologic Studies on Neural Mechanisms of Visual Localization and Discrimination.
- Dr. Ludwig von Sallmann, New York, Experimental Contributions to the Problem of Vitreous Detachment.
- Drs. William L. Benedict and Edith M. Parkhill, Rochester, Minn., Gliomas of the Retina: Histogenesis and Histopathologic Classification.

Annual Golf Tournament at Cleveland.—The executive committee of the American Medical Golfing Association has added new features to the annual tournament which will be held at Cleveland, Monday June 2, during the annual session of the American Medical Association. There will be sectional contests, for example, between surgeons, internists, orthopedists and other specialists, with a permanent prize to the winner, which will bear the crest of the American Medical Association, the name of the donor and the name of the winner. The eighteen hole players this year will have as many prizes as the thirty-six hole players, and eighteen holes played morning or afternoon will count for the sectional prizes. Those who expect to play should register now with Bill Burns, secretary, American Medical Golfing Association, 2020 Olds Tower, Lansing, Mich. Headquarters will be maintained all day Sunday and Monday, June 1 and 2, in the lobby of the Hotel Statler. The tournament will be played over two of the best golf courses in the Cleveland area, and the local committee has arranged many features of entertainment. Additional information concerning the tournament was published in THE JOURNAL, April 26, page 1935. All male Fellows of the American Medical Association are cordially invited to become members of the American Medical Golfing Association.

National Science Fund.—The National Academy of Sciences has announced the organization of a National Science Fund as a foundation to receive gifts for the advancement of science. The fund, directed by a joint board made up of scientists selected from the academy membership and distinguished laymen, is designed to permit donors who wish to

promote human welfare through support of scientific research to take advantage of the facilities of the academy and of its agency, the National Research Council. The National Science Fund has been organized as the result of a three year study of the present sources of financial support for fundamental research in science, which showed the need to develop additional funds for scientific research. The committee making the study, financed by a grant from the Carnegie Corporation of New York, found that universities and foundations which in the past have been a main support of fundamental scientific research are finding it difficult to provide the necessary funds. Although expenditures for scientific research by industry and by government have increased greatly in recent years, this expansion has not covered, nor can it hope to cover adequately the fields of fundamental research which have derived support largely from other sources, the release said. Twelve lay members were appointed to the first board of directors and twenty scientific directors were named from the academy's own membership. William J. Robbins, director of the New York Botanical Garden, is acting chairman of the board.

Section Chairmen for National Nutrition Conference.—Federal Security Administrator Paul V. McNutt has announced the chairmen of sections which will convene in the afternoon sessions of the National Nutrition Conference for Defense in Washington, D. C., May 26-28. The sections will consider definite aspects of nutrition and will formulate recommendations for consideration by all the delegates. The sections and their chairmen are:

Research and national nutrition problems: Elmer V. McCollum, Sc.D., professor of biochemistry, Johns Hopkins University School of Hygiene and Public Health, Baltimore, chairman.

Economic policy and social responsibility: Miss Lucy Gillette, Community Service Society, New York, and Hazel Kirk, Ph.D., associate professor of home economics, University of Chicago, co-chairmen.

Public health and medical aspects of nutrition (with special reference to needs of women and children): Drs. Russell M. Wilder, Rochester, Minn., chairman of the committee on food and nutrition of the National Research Council, and Richard M. Smith, Boston, president of the American Academy of Pediatrics, co-chairmen.

Nutrition for defense workers in industry: Dr. Frank G. Boudreau, executive director, Milbank Memorial Fund, New York, chairman.

Methods of general education in nutrition: Miss Dorothy Williams, Cornell University, Ithaca, N. Y., and Miss Mildred Weigley Wood, director of home economics education, public schools, Phoenix, Ariz., co-chairmen.

Professional nutrition: Lydia J. Roberts, Ph.D., professor of home economics, and Dr. John H. Musser, of Louisiana School of Medicine, New Orleans, co-chairmen.

Distribution and processing of foods (with reference to consumer problems): Lawrence V. Burton, New York, editor of *Food Industries*, and Hector Lazo of the Cooperative Food Distributors of America, co-chairmen.

Community planning for nutrition: Mr. Howard F. McCloskey of the American Youth Commission and Harry C. Ramsower, director of the agricultural extension division, Ohio State University, Columbus, co-chairmen.

General sessions of the conference will be held each morning. Among government officials who will participate are Vice President Henry A. Wallace; Secretary of Agriculture Claude R. Wickard; Secretary of Labor Frances Perkins; Brig. Gen. Lewis B. Hershey, director of the Selective Service System; Milburn L. Wilson, director of extension work, U. S. Department of Agriculture; Surgeon General Thomas Parran, U. S. Public Health Service; Assistant Secretary of State Adolf A. Berle Jr.; Miss Harriet Elliott of the Office of Price Administrator and Civilian Supply; Dr. William H. Sebrell Jr., U. S. Public Health Service; Louise Stanley, Ph.D., chief of the Bureau of Home Economics; Helen Mitchell, Ph.D., director of nutrition for the Federal Security Agency; Miss Edna P. Amidon of the Office of Education and Dr. Martha M. Eliot of the Children's Bureau, U. S. Department of Labor. Others who will address general sessions include Mrs. Franklin D. Roosevelt; John R. Murlin, Ph.D., professor of physiology, University of Rochester, Rochester, N. Y.; Henry C. Sherman, Ph.D., professor of nutrition, Columbia University, New York, and Dr. Wilder.

CANADA

Cancer Services in Alberta.—Dr. George H. Malcolmson, Edmonton, has been appointed director of cancer services for the province of Alberta. He will establish two diagnostic and treatment centers for the present, each with an internist, a surgeon, a pathologist and a radiologist. The government has made available \$50,000 for the work. Treatment for the present will be limited to radium and roentgen ray treatment in curable cases, according to the *Canadian Medical Association Journal*.

Postgraduate Course in Winnipeg.—Dr. James S. McCartney, associate professor of pathology, University of Minnesota Medical School, Minneapolis, was the guest speaker at a postgraduate course offered by the University of Manitoba

Faculty of Medicine in Winnipeg, recently. Dr. McCartney took part in several discussions and addressed the Winnipeg Medical Society on "Pulmonary Embolism and Thrombosis."

LATIN AMERICA

Congress of Plastic Surgery.—The First Latin American Congress of Plastic Surgery will be held in Rio de Janeiro and São Paulo, Brazil, July 6-12, under the sponsorship of the Latin American Society of Plastic Surgery. Dr. Antonio Prudente, São Paulo, is president of the congress, and correspondence may be directed to him at Rua Benjamin Constant, 171-1.

Urologists Honored.—Drs. William F. Braasch, Rochester, Minn., Joseph F. McCarthy and Robert Gutierrez, New York, were made members of the Cuban Society of Urology at a meeting in Habana recently. All were present and presented papers as follows: Dr. Braasch, "Hypertension and Surgical Kidney"; Dr. McCarthy, "Instrumental Surgery on the Superannuated," and Dr. Gutierrez, "Surgery of Prostatic Stones."

Society News.—The first national congress of school health for Brazil was held in São Paulo, April 21-27, according to *Brasil-Médico*. Official themes included organization and orientation of school health services, physical and mental health of teachers, morbidity and mortality among students, the problem of repeaters in the primary schools, mental hygiene and nutrition.—Dr. Leonard Averett, Philadelphia, addressed the Cuban Obstetrical and Gynecologic Society in Habana recently on "Vaginal versus Abdominal Hysterectomy." He also conducted an operative clinic at the Mercedes Hospital.—Dr. Albert B. Sabin, Cincinnati, addressed members of the Finlay Institute and the Cuban Microbiological Society in Habana, April 7, on "The Nature of Human Poliomyelitis."

Government Services

Physicians Wanted for the CCC

Vacancies now exist in the CCC in the Eighth Corps Area (Colorado, Arizona, New Mexico, Oklahoma and Texas) wherein the services of physicians can be utilized as camp physicians. Applicants for these positions must be graduates of approved medical schools, must be licensed to practice medicine in at least one state and must be physically qualified. Applications should be addressed to the surgeon, CCC Headquarters, Eighth Corps Area, Fort Sam Houston, Texas. If selected, physicians must report to their first duty station at their own expense and, on being relieved from duty, return transportation must also be at the expense of the individual. They will be required to furnish necessary medical treatment to the personnel of CCC camps and in addition will be required to perform such other duties as may be directed by their superior officers.

Dr. Coffey Named Assistant Surgeon General

Dr. Erval R. Coffey, formerly assistant chief, domestic quarantine division, U. S. Public Health Service, has been appointed assistant surgeon general to head the division of sanitary reports and statistics. Dr. Coffey's new work will include direction of public relations for the health service. Dr. Coffey graduated at the University of Kansas School of Medicine in 1923, joining the public health service May 24, 1924 with the rank of assistant surgeon. His service includes inspection of immigrants at Ellis Island, direction of health activities for the Mississippi River flood refugees, as director of local health services, Missouri State Department of Health, southeastern Missouri, and malarial investigation in the field office of the public health service at Richmond, Va. From May 1933 to June 1937 he served as state director of health of Washington on loan from the federal service, reorganizing Washington's health services at the request of the state. From June 1937 until September 1938 Dr. Coffey administered federal grants-in-aid to the states of New York, New Hampshire, Maine, Vermont, Connecticut, Massachusetts, Rhode Island, New Jersey and Pennsylvania, as regional consultant of the U. S. Public Health Service. He undertook this work on a national scale as assistant chief of the domestic quarantine division. He is a member of the governing council of the American Public Health Association.

Foreign Letters

LONDON

(From Our Regular Correspondent)

March 22, 1941.

Bombing Hospital Ships

The British Admiralty announces that the standards of conduct exhibited by the enemy in the warfare in the Mediterranean area has undergone a distinct change since it became necessary for Germany to render assistance to Italy. On two occasions recently the hospital ship *Dorsetshire* has been attacked by German aircraft. Fortunately the ship was not hit on either occasion. The *Dorsetshire* is clearly labeled a hospital ship and its identity as such has been made known to the enemy in accordance with the requirements of international law.

During the first seven months of the war against Italy, Malta was subjected to many air attacks, but in none were deliberate attacks made on the hospitals. Since the appearance of German aircraft in the central Mediterranean the Intarfa hospital at Malta has been deliberately attacked. Even Germany's ally has suffered. On the afternoon of January 8 a merchant ship evacuating Italian prisoners of war from the Libyan coast was attacked by two enemy aircraft, believed to have been German. This resulted in a large number of casualties to the Italian prisoners, many of which were fatal. When the British captured the important Libyan port of Benghazi the Italians announced that they had surrendered the town in order to avoid damage to private property and loss of life among the civilian population. This shows that the frequent British air attacks, made before the surrender, had been confined to military objectives. But since the British occupation Benghazi has been subjected to repeated air attacks by German aircraft. These attacks have caused loss of life among the Italian civilian population and damage to private property in the residential quarters.

War Injuries of the Spine

At the Section of Surgery of the Royal Society of Medicine, Mr. Julian Taylor discussed war injuries of the spine. His experience during the last war showed that they fell into two classes—the larger, which might be called the civil group, in which automobiles or falling masonry were the usual causes, and the smaller, due to projectiles. The damage to the cord and the effect on the functions were similar in the two classes and there was a high proportion of neurologically complete interruptions. There might be complete severance, physiologic interruption due to crushing without severance or what is called spinal concussion or shock. These were instantaneous events, but at the site of crushing, bleeding usually occurred later and tended to spread up and down the substance of the cord in more or less cylindric form, producing later cavities containing clear fluid.

The effect on the conductivity of the cord might be transient except in cases of severance. But, as Sergeant and Trotter found, no return of function occurred after early complete paraplegia. Hemorrhage into the substance of the cord might produce increasing interruption, due at first to continued effusion of blood and later to the reaction to its presence. A partial lesion might be recognized by persistence below its site of sensibility, motor power or reflex activity. It indicated that the violence which reached the cord was slight, and useful recovery might be hoped for; but it might take a year or more. These partial lesions were the only ones worth operative or manipulative treatment with a view to relieving pressure. Experience in the present war suggested that they were of great rarity in both the classes mentioned. In less than one sixth of the projectile cases the question of surgical relief might

be considered, but in the majority, even of these, it was likely ultimately to be rejected.

In an incomplete lesion the presence of metallic or bony fragments might cause persistent pressure on the cord, and these fragments should be removed. It was rare for a metallic fragment to be held up in the spinal canal, for the energy necessary to penetrate the canal or fracture its walls would usually carry it out again. A reason for removing metallic fragments irrespective of position was the prevention of infection. When entrance wounds were suppurating freely they should be rendered as clean as possible by a superficial drainage operation before removing the foreign body. In penetrating wounds of the central nervous system meningitis was common in neglected cases. In staphylococcal meningitis sulfapyridine was useful.

In at least 5 cases out of 6, transport, nursing and management of the bladder were the beginning and end of treatment. For retention of urine three methods were available: regular catheterization, the tied-in catheter and suprapubic drainage. Each had its disadvantages. For the patient who might recover vesical function he recommended the first, and also for the one likely to develop automatic micturition. For the one not going to improve (for example one with a lesion of the cauda equina) he recommended suprapubic cystostomy with lavage at low pressure. For the one who had to travel a long distance in an ambulance a tied-in catheter, scrupulously arranged, was probably the least harmful.

Decentralization of Health Services

Measures to deal with attacks from the air on the civilian population and the threat of invasion include decentralization of the local government normally exercised at Whitehall, London. The country has been divided into twelve districts, each in charge of a regional commissioner, who ensures coordination between the local authorities and the new organization of a million civil defense workers—wardens, shelter marshals, police, fire fighters, rescue and demolition men and civil defense cadets. In this scheme the Ministry of Health plays an important part. It has primary responsibility for rest centers, evacuation and billeting, health hostels and housing, hospitals and first aid posts, sanitation and water supply. The reception of thousands of mothers and children in the countryside has demanded the provision of clubs, nursery centers, communal feeding, bathing and laundries, and an emergency maternity service. Several stately homes are now put to new purposes. Sixty houses, with a capacity for three thousand births a month, are maintained for London mothers alone. Nursing staffs are usually drawn from town hospitals, and nearly everywhere the medical arrangements have proved to be above criticism. The clash of standards between urban and rural authorities has already effected substantial improvement in parts of the countryside.

In evacuation or target areas the education department, with its buildings and its administrative, medical and domestic science staffs, has rendered valuable service in manning rest centers. With the help of the Ministry of Food, cook-houses, municipal feeding and mobile canteens are speedily adapted from school and communal feeding to an emergency service.

Hospitals' Radon Center

As the result of the gift from the British War Relief Society of New York, further supplies of radon are now assured. The gift was made to the British Hospitals Association, which has asked the Middlesex Hospital (whose association with radiotherapy is well known) to administer it. In the first instance it will be necessary to make a charge for the radon, but this has been fixed at the lowest rates obtaining at the Medical Research Council: 24 cents a millicurie, with a reduction to 12 cents for any quantity in excess of 50 millicuries. It is hoped that some arrangement will soon be possible by which the burden of such payments can be lightened.

Deaths

Frank B. Young * Long Beach, Calif.; Kansas City (Mo.) Medical College, 1900; member of the state board of health; was president of the Long Beach Academy of Medicine and secretary of the Harbor Branch of the Los Angeles County Medical Society; vice president of the executive staff of the Community Hospital; member of the staffs of the Seaside and St. Mary's hospitals, Long Beach, and of the Hollywood Hospital; police surgeon; at one time director and president of the state board of health of Arkansas; past president of the state board of medical examiners of Arkansas; formerly physician in charge of the State Hospital for Nervous Diseases, Little Rock; past president of the Scottsbluff County (Neb.) Medical Society; formerly on the staff of the Methodist Hospital, Scottsbluff, Neb.; lieutenant commander of the medical reserve corps of the United States Navy; aged 62; died, March 5, of cerebral hemorrhage.

Thomas A. Woodruff * New London, Conn.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1888; third vice president of the American Medical Association in 1908, and member of its House of Delegates in 1909, 1910 and 1913; past president of the Chicago Ophthalmological Society; member of the American Academy of Ophthalmology and Otolaryngology and of the Association for Research in Ophthalmology; served during the World War; fellow of the American College of Surgeons; consulting ophthalmologist, Lawrence and Memorial Associated Hospitals; formerly ophthalmic surgeon, St. Luke's Hospital and St. Anthony de Padua Hospital, Chicago; co-author of "Commoner Diseases of the Eye"; aged 75; died, April 15, of chronic endocarditis.

Cyril K. Valade * Detroit; Detroit College of Medicine and Surgery, 1916; member of the American Academy of Dermatology and Syphilology; past president of the Detroit Dermatological Society; served during the World War; instructor in dermatology and syphilology at the Wayne University College of Medicine; aged 49; at various times and in various capacities served on the staffs of the Receiving Hospital, St. Joseph's Mercy Hospital and the Harper Hospital, where he died, March 26, of coronary thrombosis.

Frederick Leslie Benton * Medical Inspector, Commander, United States Navy, retired, Washington, D. C.; Columbia University College of Physicians and Surgeons, New York, 1896; Universidad de la Habana Facultad de Medicina y Farmacia, Cuba, 1907; fellow of the American College of Surgeons; entered the navy in 1898 and retired Dec. 1, 1929; on the staffs of the Episcopal Eye, Ear and Throat Hospital and the George Washington University Hospital; aged 66; died, April 8, of a self-inflicted bullet wound.

William Fitch Cheney * San Francisco; Cooper Medical College, San Francisco, 1889; clinical professor of medicine from 1909 to 1932 and since 1932 emeritus professor at the Stanford University School of Medicine; member of the American Gastro-Enterological Association; fellow of the American College of Physicians; formerly professor of principles and practice of medicine at his alma mater; aged 74; died, April 10.

John Joseph Dailey * McAdoo, Pa.; Medico-Chirurgical College of Philadelphia, 1905; past president of the Schuylkill County Medical Society; served during the World War; was president of the board of health of McAdoo; past president of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital; medical director of the public schools; aged 57; died, March 28, of coronary thrombosis.

Leslie Rutherford * Peoria, Ill.; Rush Medical College, Chicago, 1901; president of the city board of health; past president of the Peoria City Medical Society; chief physician for the draft board; at various times president of the staffs of the Proctor Hospital and the Methodist Hospital; aged 61; died, March 28, in the James M. Jackson Memorial Hospital, Miami, Fla., of cerebral hemorrhage.

Clifford Rispin Orr * Buffalo; University of Buffalo School of Medicine, 1898; assistant professor of radiology at his alma mater; member of the Radiological Society of North America and the American College of Radiology; served during the World War; for many years on the staff of the Edward J. Meyer Memorial Hospital; aged 74; died, March 15, of coronary thrombosis.

Benson Blake Martin * Vicksburg, Miss.; Tulane University School of Medicine, New Orleans, 1898; fellow of the American College of Surgeons; medical director and superintendent of the Vicksburg Infirmary; aged 64; died, March 9, in the Baptist Hospital, New Orleans, of obstruction of the common bile duct, cirrhosis of the liver and toxemia.

Arthur Jesse Edgar Decker, Illmo, Mo.; Central Medical College of St. Joseph, 1899; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; served during the World War; aged 73; died, March 8, in the Veterans Administration Facility, Jefferson Barracks, of heart disease and chronic nephritis.

William Dunn Madden, Clinton, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; member of the Iowa State Medical Society; served during the World War; at one time coroner of Cascade County, Mont.; aged 64; died, March 29, in the Mercy Hospital of cerebral hemorrhage.

Charles Walton Sheldon, Wellsboro, Pa.; Medico-Chirurgical College of Philadelphia, 1904; member of the Medical Society of the State of Pennsylvania; at one time medical director of Tioga County; president of the Tioga County Medical Society; aged 64; died, March 2, in St. Petersburg, Fla., of coronary thrombosis.

Roland Bain Macon, Clarksville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1898; Jefferson Medical College of Philadelphia, 1901; member of the Tennessee State Medical Association; for many years chairman of the medical committee of the Clarksville Hospital; aged 65; died, March 15, of heart disease.

Marion Lee Compton, Augusta, Ga.; University of Texas School of Medicine, Galveston, 1917; member of the American Psychiatric Association; fellow of the American College of Physicians; served during the World War; on the staff of the Veterans Administration Facility; aged 46; died, March 27, of heart disease.

Edwin Hicks Van Deusen * Vineland, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1880; past president of the Cumberland County Medical Society; on the staff of the Newcomb Hospital; aged 81; died, March 20, in the Orlando (Fla.) Hospital of coronary occlusion and arteriosclerosis.

John Irvine McKelway, Orofino, Idaho; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the American Psychiatric Association; served during the World War; superintendent of the State Hospital; aged 65; died, April 7, of carcinoma of the throat and coronary thrombosis.

Fernande Hachatt Luck, Indianapolis; Indiana University School of Medicine, Indianapolis, 1912; at one time assistant university physician at Indiana University; formerly state physician at the Indiana Woman's Prison and the Indiana Girls' School; aged 50; died, March 25, of cerebral hemorrhage.

Gilbert McClellan Mason * Boston; Boston University School of Medicine, 1898; served during the World War; demonstrator in anatomy at his alma mater from 1901 to 1910; formerly on the staffs of the Carney and Forest Hills hospitals; aged 68; died, March 17, of coronary thrombosis.

William Guy Townsend * Acting Assistant Surgeon Lieutenant (j. g.) United States Navy, retired, Baltimore; University of Maryland School of Medicine, Baltimore, 1888; entered the navy Aug. 24, 1921 and retired Sept. 1, 1935; aged 76; died, March 12, of carcinoma of the prostate.

Thomas Molloy Harris, Pilot Point, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1901; member of the State Medical Association of Texas; past president of the Denton County Medical Society; aged 62; died, March 18, of cerebral hemorrhage.

Charles S. Parker, Kings Park, N. Y.; Syracuse University College of Medicine, 1909; member of the Medical Society of the State of New York and the American Psychiatric Association; superintendent of the Kings Park State Hospital; aged 54; died, March 28, of chronic myocarditis.

Francis Hebron Husband * Sault Ste. Marie, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1901; fellow of the American College of Surgeons; on the staff of the Chippewa County War Memorial Hospital; aged 63; died, March 16, of monocytic leukemia.

LaMott Fair Bates * Durand, Mich.; University of Michigan Medical School, Ann Arbor, 1924; for many years president of the school board; past president of the Shiawassee County Medical Society; on the staff of the Durand Hospital; aged 39; died, April 5, of cerebral hemorrhage.

Samuel Marion Stone, Charleston, W. Va.; University of the South Medical Department, Sewanee, Tenn., 1904; Medical College of Virginia, Richmond, 1916; on the staff of the Charleston General Hospital; aged 60; died, March 16, of carcinoma of the pleura and Buerger's disease.

Joseph Lemen Reeve, Edwardsport, Ind.; University of Louisville (Ky.) Medical Department, 1881; member of the Indiana State Medical Association; county health officer; formerly member of the state legislature; aged 83; was found dead, March 13, of chronic myocarditis.

Jonathan Clinton Foltz, New Haven, Conn.; University of Pennsylvania Department of Medicine, Philadelphia, 1888; formerly surgeon, United States Public Health Service reserve; served during the World War; aged 76; died, April 13, in Corpus Christi, Texas, of pneumonia.

Alfred Cole Wallin Ⓢ Matawan, N. J.; Columbia University College of Physicians and Surgeons, New York, 1896; on the staff of the Dr. E. C. Hazard Hospital, Long Branch; member of the board of health of Matawan; aged 70; died, March 10, of cerebral hemorrhage.

Milton Waldrop Robertson, Corinth, Miss.; Birmingham Medical College, 1915; member of the Mississippi State Medical Association; served during the World War; formerly county health officer; aged 52; died, March 2, in the McRae Hospital of massive gastric hemorrhage.

Thomas C. Moody, Lake Charles, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1894; member of the Louisiana State Medical Society; past president of the Calcasieu Parish Medical Society; aged 70; died, March 6, of angina pectoris.

Roy Daniels Stone, Sully, Iowa; Hering Medical College, Chicago, 1910; member of the Iowa State Medical Society; aged 58; died, March 25, in the Mary Frances Skiff Memorial Hospital, Newton, of hemolytic streptococcus infection of the throat and pneumonia.

Jesse Armed Strickland Ⓢ St. Petersburg, Fla.; University of North Carolina School of Medicine, Chapel Hill, 1910; past president of the Pinellas County Medical Society; on the staff of St. Anthony's Hospital; aged 60; died, March 14, of coronary occlusion.

Jesse P. Randolph, Hot Springs National Park, Ark.; St. Louis University School of Medicine, 1906; for many years county coroner; veteran of the Spanish-American War; aged 63; died, March 20, in the Army and Navy General Hospital of arteriosclerosis.

Henry August Long, Effingham, Ill.; St. Louis College of Physicians and Surgeons, 1907; member of the Illinois State Medical Society; formerly mayor of Effingham; aged 58; died, March 24, in St. Anthony's Hospital of hypertensive cardio-renal disease.

Philip Jameson Heuer, St. Louis; Washington University School of Medicine, St. Louis, 1895; on the associate staffs of the Deaconess, De Paul and Missouri Baptist hospitals; aged 69; died, March 7, of carcinoma of the stomach and gastric hemorrhage.

Austin Bell Ⓢ Hopkinsville, Ky.; University of Virginia Department of Medicine, Charlottesville, 1894; president of the Kentucky State Medical Association; veteran of the Spanish-American and World wars; aged 66; died, April 3, of coronary disease.

Richard Harrison Peake, Norfolk, Va.; Medical College of Virginia, Richmond, 1915; member of the Medical Society of Virginia; on the staff of the Leigh Memorial Hospital; aged 51; died, March 6, of chronic nephrosis and pulmonary embolus.

Roger William Moister Ⓢ Summit, N. J.; New York Homeopathic Medical College and Flower Hospital, New York, 1902; on the staff of the Overlook Hospital; aged 64; died, March 9, in Phoenix, Ariz., of pulmonary tuberculosis.

Elah Adelbert Lapham Ⓢ Phillips, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911; served during the World War; aged 58; died, March 24, of coronary thrombosis.

Elmer Ellsworth Perry, Oak Grove, Mo.; Kansas City Medical College, 1892; for many years a member of the school board; aged 75; died, March 10, in the Wesley Hospital, Kansas City, of myocarditis following influenza.

Charles Telsey, Utica, N. Y.; Long Island College Hospital, Brooklyn, 1914; member of the Medical Society of the State of New York; aged 49; on the staff of St. Luke's Hospital, where he died, March 1, of heart disease.

Samuel Goodall Panter, Lincoln, Neb.; Omaha Medical College, 1886; St. Louis College of Physicians and Surgeons, 1888; Missouri Medical College, St. Louis, 1891; aged 88; died, March 17, of gastric ulcer and hemorrhage.

Alexander Gordon MacPherson Ⓢ Grand Rapids, Mich.; Grand Rapids Medical College, 1902; College of Physicians

and Surgeons, Baltimore, 1903; served during the World War; aged 60; died, March 14, of carcinoma.

Thomas W. Oberlin Ⓢ Hammond, Ind.; Northwestern University Medical School, Chicago, 1898; past president of the Lake County Medical Society; aged 65; was killed, March 11, in an automobile accident.

Peter George Kokenes, Springfield, Ill.; St. Louis University School of Medicine, 1927; member of the Illinois State Medical Society; aged 43; died, March 7, in St. John's Hospital of cerebral hemorrhage.

James Weedin Martin, Drumright, Okla.; Missouri Medical College, St. Louis, 1879; member of the Missouri State Medical Association; aged 86; died, March 1, of chronic nephritis and myocarditis.

Thomas Aloysius Mulcahy, New York; Columbia University College of Physicians and Surgeons, New York, 1901; aged 64; died, March 3, of arteriosclerosis, hypertension and cerebral hemorrhage.

James Jay Pattee Ⓢ Pueblo, Colo.; Rush Medical College, Chicago, 1895; fellow of the American College of Surgeons; on the staff of St. Mary's Hospital; aged 72; died, March 20, of heart disease.

Charles Jesse Hutton Ⓢ Atlanta, Ill.; Barnes Medical College, St. Louis, 1911; aged 59; died, March 19, in the Evangelical Deaconess Hospital, Lincoln, of nephritis and coronary embolism.

Elmore R. Miller, Ephrata, Pa.; University of Maryland School of Medicine, Baltimore, 1892; deputy coroner and for many years county coroner; aged 72; died, March 4, of coronary occlusion.

James Wallace Weir, Sparta, Ill.; Missouri Medical College, St. Louis, 1882; member of the Illinois State Medical Society; aged 90; died, March 2, in the Community Hospital of pneumonia.

Reuben R. Roach, New Market, Tenn.; Tennessee Medical College, Knoxville, 1902; member of the Tennessee State Medical Association; aged 65; died, March 15, of cerebral hemorrhage.

Joseph Burns McPherson Ⓢ Hastings, Neb.; John A. Creighton Medical College, Omaha, 1905; at one time a police surgeon in Omaha; aged 62; died, March 10, of coronary occlusion.

William Edwin Kidd, Oak Park, Ill.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1891; aged 70; died, March 19, in the Chicago Memorial Hospital of arteriosclerosis.

Charles Beatty Kenney, East Chicago, Ind.; University of Georgia School of Medicine, Augusta, 1924; aged 39; died, March 15, in Highland of angina pectoris and hypertension.

Albert G. Huegli Ⓢ Detroit; Detroit College of Medicine, 1901; aged 62; secretary of the medical staff of the Deaconess Hospital, where he died, March 7, of intestinal obstruction.

James M. McClanahan, Kirkwood, Ill.; Chicago Medical College, 1874; member of the Illinois State Medical Society; aged 90; died, March 24, of bronchopneumonia.

Meyer B. Lichtenstein Ⓢ Pittsburgh; University of Pittsburgh School of Medicine, 1910; aged 57; died, March 11, in Miami Beach, Fla., of coronary thrombosis.

Edward E. Thomas, Coolidge, Texas; University of Dallas Medical Department, 1902; aged 70; died, March 1, of injuries received in an automobile accident.

Edward Fellmer Kopetschny, Jersey City, N. J.; Bellevue Hospital Medical College, New York, 1886; aged 78; died, March 23, of coronary thrombosis.

Emil F. R. Liebrecht, Chicago; Jenner Medical College, Chicago, 1912; aged 78; died, March 23, in the Illinois Masonic Hospital of coronary thrombosis.

Charles C. Neff Ⓢ York, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; aged 69; died, March 4, of coronary occlusion.

Edgar Braxton Provine, Grenada, Miss.; Memphis (Tenn.) Hospital Medical College, 1899; aged 66; died, March 12, of cirrhosis of the liver.

Woodruff A. Banks, Chattanooga, Tenn.; Chattanooga Medical College, 1906; aged 59; died, March 21, of myocarditis and diabetes mellitus.

Lunsford Hoxsey Lewis, Elkton, Va.; Medical College of Virginia, Richmond, 1910; aged 60; died, March 8, of a self-inflicted bullet wound.

Bureau of Investigation

REPEATER REPEATS

In *THE JOURNAL*, Feb. 1, 1941, the Bureau of Investigation disclosed the activities of an impostor, one Aaron W. Raffelson, who had been previously described in these pages in 1934. The files of the Bureau contain the names of many persons who frequently repeat their activities as impostors. With each new

The photographs reproduced above were taken by the New York City authorities in 1930. The center picture is a reproduction of one taken by the New Mexico authorities in 1934. The photographs reproduced below were taken in April 1941 by the California authorities.

offense publicity is given in the hope that publication of their pictures and the data concerning them will militate against further repetition of their performances.

Once again the California Board of Medical Examiners is to be congratulated on the rapidity with which it is able to take action against medical impostors. On Dec. 9, 1940, a physician in Newman, Calif., informed the board that an individual who was employed as a bacteriologist at the California Milk Products Company in Gustine, Merced County, was posing as a physician licensed in another state. The doctor's suspicions were aroused when he noted that the bacteriologist was dyeing his hair red, but further information was not received at that time.

On April 9, 1941, this physician informed the board by long distance telephone that the bacteriologist had been identified through a picture appearing in *THE JOURNAL* for February 1 as Aaron W. Raffelson. Raffelson was first employed by the company in October 1940. He had assisted a physician in Gustine in giving anesthetics and advice and had treated the physician's wife for bronchitis. He had married a Gustine school teacher on Jan. 31, 1941, at Reno, Nev.

The investigator for the board, T. P. Hunter, states that Raffelson accounted for the four years spent in the New Mexico State Penitentiary by stating that he had studied in Vienna during that time and had served with the Loyalist forces during the Spanish war. On the strength of this claim, he had addressed a local club on his experiences in Spain, despite the fact that he had never seen that country.

According to this same investigator, when the February 1 issue of *THE JOURNAL* arrived in Gustine, Raffelson carefully called at each doctor's office, borrowed that issue of *THE JOURNAL*, tore out page 433 and defaced numbers of adjacent pages so that the numbers of the pages would not be noticed. However, one copy of *THE JOURNAL* had arrived with its wrapper torn off, and the local postmistress, in leafing through the magazine, had noticed Raffelson's picture and informed his employer. The employer confronted Raffelson with the article, and the latter admitted the truth of the statements but explained that he had been forced to leave New York University School of Medicine because he had committed an abortion under the name of Aaron W. Raffelson, and that he had gone to the University of Colorado and enrolled there under his true name, which, he claimed, was that of the physician whose diploma he held. He further told his employer that after he had received his diploma he was afraid to practice under this "true" name because of his record in New York, but he insisted that he was a bona fide graduate physician.

On April 9 Raffelson told the investigator for the California board that he had had one year's medical training at New York University and had forged credentials of a fellow student and had obtained junior standing at the University of Colorado, and finally that the diploma which he held was bona fide. He agreed, however, to surrender the document on the basis of its having been obtained on forged credentials. Some forty minutes later he changed his story and stated that the diploma was not bona fide and that he had had it printed in Amarillo, Texas, during August 1940, that his true name was David Dressler (another pseudonym which he has used in the past; incidentally, the real David Dressler is an officer of the state of New York) and that under this name he had attended New York University School of Medicine for three years. He signed a statement to this effect, and twelve minutes later stated that Dressler was not his true name but that he did not care to give his true name and that the name of the physician appearing on the diploma was not his true name.

He admitted having been in Colorado following his release from the New Mexico State Penitentiary in February 1939, at which time he had posed as a New York physician (see previous article in *THE JOURNAL*). He also stated that he had lived with a young woman in Denver for seven months but had never been married to her.

A complaint was issued, charging Raffelson with two violations of the Business and Professions Code of California, and a warrant was issued. Raffelson was arrested and, when searched, was found to have a 1/8 ounce bottle of strychnine sulfate in his possession. The investigator stated that Raffelson intimated that he had contemplated suicide. He was transported to Merced and booked in the Merced County sheriff's office as 883 (see accompanying photographs).

When Raffelson was brought to court, he pleaded guilty to one count of the charge, while the second count was dismissed on motion of the district attorney. He waived time for passing sentence, and the court ordered him to be confined in San Quentin State Prison for the term prescribed by law (one to three years). In answering the routine questions of the court before imposition of sentence, he claimed that his true name was David Dressler, that he was born in 1906 in Dublin, Ireland, coming to the United States in 1908, and that he had received a bachelor's degree from the University of London, England, having been a resident there from 1922 to 1926. 11:

claimed to have had three years' medical training in some New York medical school which he refused to name. He stated that he had a heart deficiency and at present was taking a daily maintenance dose of digitalis but that otherwise he was healthy.

The diploma which Raffelson had in his possession was found, in fact, to be a bona fide diploma which was apparently stolen from the physician to whom it belonged. It will be recalled that when Raffelson was in Denver he married a Denver girl, but information received since the publication of the last article indicates that that marriage was annulled on Dec. 21, 1940. Reproduced with this article are photographs, the first group taken by the New York authorities in 1930, the second by New Mexico authorities in 1934, and finally a current one taken by the California authorities.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS

EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in *THE JOURNAL*, May 17, page 2336.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 17-19. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: Phoenix, July 1-2. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: * Medical. Little Rock, June 5-6. Sec., Dr. D. L. Owens, Harrison. Eclectic. Little Rock, June 5-6. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, July 14. Written. San Francisco, June 30-July 3. Sec., Dr. Charles B. Pinkham, 1020 N St., Sacramento.

COLORADO: Denver, July 18. Applications must be on file not later than June 15. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: * Medical. Written. Hartford, July 8-9. Endorsement. Hartford, July 22. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Homeopathic. Derby, July 15-16. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: July 8-10. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

FLORIDA: Jacksonville, June 23-24. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, June. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, July 14-17. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

ILLINOIS: Chicago, June 24-26. Supt. of Registration, Mr. Lucien A. File, Department of Registration and Education, Springfield.

INDIANA: Indianapolis, June 17-19. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, Citizens Trust Bldg., Fort Wayne.

IOWA: Iowa City, June 3-5. Dir., Division of Licensure and Registration, State Department of Health, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

KANSAS: Kansas City, June 17-18. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Louisville, June 5-7. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

LOUISIANA: New Orleans, June 12-14. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

MAINE: Augusta, July 1-2. Sec., Board of Registration in Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Medical. Baltimore, June 17-20. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. Homeopathic. Baltimore, June 17-18. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, July 8-11. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Ann Arbor and Detroit, June 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MISSISSIPPI: Jackson, June 25-26. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MISSOURI: St. Louis, May 29-31. Sec., State Board of Health, Dr. Harry F. Parker, State Capitol Bldg., Jefferson City.

NEBRASKA: Omaha, June 12. All applications must be on file not later than May 29. Dir., Mrs. Jeanette Crawford, 1009 State Capitol Bldg., Lincoln.

NEW HAMPSHIRE: Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, June 17-18. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 13-14. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 23-26. Chief, Bureau of Professional Examinations, 315 Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 16-20. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, July 1-4. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: Practical. June 11 and 14. Written. June 12-13. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: Oklahoma City, June 11-12. Sec., Dr. James D. Osborn Jr., Frederick.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 8-12. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. Marguerite G. Steiner, 358 Education Bldg., Harrisburg.

RHODE ISLAND: July 10. Acting Chief, Division of Examiners, Mr. E. Clyde Thomas, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 23-25. Sec., Dr. A. Earle Booser, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, July 15-16. Dir., Medical Licensure, Dr. J. F. D. Cook, State Board of Health, Pierre.

TEXAS: Austin, June 16-18. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas.

VERMONT: Burlington, June 17-19. Sec., Dr. F. J. Lawliss, Richford.

VIRGINIA: Richmond, June 17-20. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WASHINGTON: Seattle, July 21-23. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

WEST VIRGINIA: Wheeling, July 7-9. Sec., Public Health Council, Dr. C. F. McClintic, State Capitol, Charleston.

WISCONSIN: Milwaukee, June 24-27. Sec., Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, June 2-3. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Tucson, June 17. Sec., Mr. Franklin E. Roach, Science Hall, University of Arizona, Tucson.

CONNECTICUT: June 14. Address State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, Oct. 20-21. Sec., Dr. George C. Ruhland, 203 District Bldg., Washington.

IOWA: Des Moines, July 8. Dir., Division of Licensure and Registration, State Department of Health, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

OREGON: Corvallis, July 12. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Aug. 20. Acting Chief, Division of Examiners, Mr. E. Clyde Thomas, 366 State Office Bldg., Providence.

SOUTH DAKOTA: June. Sec., Dr. G. M. Evans, Yankton.

WASHINGTON: Seattle, July 17-18. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

WISCONSIN: Milwaukee, June 7. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

Minnesota January Report

The Minnesota State Board of Medical Examiners reports the written examination for medical licensure held at Minneapolis, Jan. 21-23, 1941. The examination covered 12 subjects and included 60 questions. An average of 75 per cent was required to pass. Forty-eight candidates were examined, all of whom passed. Two physicians were licensed to practice medicine by reciprocity and 2 physicians so licensed by endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
George Washington University School of Medicine...	(1937)		87.3
Northwestern University Medical School...	(1938) 91.1,	(1939)	87.4

MEDICOLEGAL ABSTRACTS

Taxes (Federal Income): Accounts Receivable as Gross Income for Taxable Year in Which Death Occurs.—In this case the Supreme Court of the United States held that the fair value of the interest of a decedent physician, who had kept his accounts on a calendar year cash receipts and disbursements basis, in the accounts receivable of a partnership of physicians of which he had been a member must be included, for federal income tax purposes, in his gross income for the taxable year in which death occurred, even though the accounts receivable represent uncollected charges for services rendered in preceding taxable years or may not be collected until some subsequent calendar year. This holding, in the opinion of the Supreme Court, necessarily is called for by 26 U. S. C. A., Internal Revenue Code, Section 42, reading in part as follows:

In the case of the death of a taxpayer there shall be included in computing net income for the taxable period in which falls the date of his death, amounts accrued up to the date of his death if not otherwise properly includible in respect of such period or a prior period.

In the present case, the decedent's death effected a dissolution of a partnership of physicians. Both the decedent and the partnership were on a calendar year cash receipts and disbursements basis. When decedent died about \$69,000 of partnership accounts receivable were outstanding for services rendered to patients during the decedent's lifetime. The decedent's interest in the accounts receivable at their face value was approximately \$27,000. The Commissioner of Internal Revenue set a fair value of that interest at one fifth of its face value—approximately \$5,400—and held that the latter amount must be regarded as a portion of the decedent's gross income for the last taxable year of his life and be taxed accordingly. The commissioner's action was affirmed on successive appeals by the Board of Tax Appeals, the circuit court of appeals, second circuit, and by the United States Supreme Court.—*Pfaff et al. v. Commissioner of Internal Revenue*, 113 F. (2d) 114; 61 S. Ct. 783 (1941).

Malpractice: Liability of Dentist for Failure to Take Roentgenograms Following Dental Extraction.—The plaintiff, who was suffering from rheumatism or arthritis, on the advice of her attending physician consulted the defendant dentist as to the advisability of having some of her teeth extracted. The defendant made a roentgenogram of the plaintiff's teeth and determined that eleven of her upper teeth should be removed. Accordingly, on Feb. 13, 1938, he extracted the eleven teeth under a general anesthetic and advised the plaintiff to use a warm mouth wash and to apply alternating hot and cold applications to her face after she returned home. That evening the defendant called at the plaintiff's home and removed a piece of tooth or bone which was protruding from the upper jaw and advised her to continue the mouth wash. The defendant discharged the plaintiff early in March after telling her husband that he had made a "clean job" of the operation and that no roots had been left in her mouth. The defendant later referred her for the fitting of a dental plate to Dr. Ruth, a prosthodontist who, after several visits and treatments, fitted the plaintiff with a temporary plate on March 12. At that time Dr. Ruth observed nothing wrong with the plaintiff's mouth or gums that contraindicated the installation of the plate. The following October the plaintiff returned to Dr. Ruth and complained that the plate did not fit. Dr. Ruth then made a roentgen examination of the plaintiff's mouth and discovered that fragments of the roots of six of the extracted teeth still remained in the plaintiff's jaw. After these roots were extracted it was necessary to install a new plate. Subsequently the plaintiff sued the defendant for damages and obtained a judgment in her favor. The dentist then appealed to the Supreme Court of Appeals of Virginia.

The plaintiff contended that the defendant was negligent in performing the operation in such a manner that the roots remained in her jaw and in failing to disclose to her that the roots still remained when he knew, or should have known, otherwise. A dentist, said the court, does not guarantee or warrant

a cure, and a bad result or a failure to cure is not in itself sufficient to raise an inference or presumption of negligence. Also, a dentist is not required to exercise the highest degree of care and skill known to the profession. On the contrary he is required only to exercise such reasonable and ordinary skill and diligence as are ordinarily exercised by the average of the members of the profession in good standing, in similar localities and in the same general line of practice, regard being had to the state of dental science at the time. In the judgment of the court there was no evidence that the defendant had been negligent in the manner in which he performed the operation or in his treatment of the plaintiff. Neither was there evidence that an examination of the plaintiff's mouth after the operation would have disclosed the presence of the broken roots in her jaw nor was there evidence that an inspection of the extracted teeth would have disclosed that some parts of the roots had been broken off and probably remained in the jaw. The court agreed with the plaintiff that the true condition of her mouth could have been discovered immediately after the operation by the taking of another roentgenogram, but it could not agree with the plaintiff's further contention that the defendant was negligent in failing to make such a roentgen examination. There was, continued the court, no evidence that it was the usual and approved custom and practice of dentists in the community in which the defendant practiced to make a roentgen examination after an extraction, and it cannot be said as a matter of law that it should have been done in the present case. The mere fact that the defendant told the plaintiff's husband that the operation was a success, when in fact he was mistaken, did not prove that the lack of success was in any way due to his negligence. Furthermore, said the court, it cannot be said, as the plaintiff further contended, that the defendant was under an obligation to disclose to the plaintiff that the roots still remained in her jaw or that he concealed that condition from her, because there was not the slightest evidence that the defendant himself had knowledge of that condition. The judgment for the plaintiff was therefore reversed.—*Alexander v. Hill*, 6 S. E. (2d) 661 (Virginia, 1940).

Workmen's Compensation Acts: Right of an Injured Employee to Select His Own Physician.—Under the workmen's compensation act of Idaho, said the Supreme Court of that state, the liability of an employer to pay expenses incurred by an employee for medical treatment is contingent on the failure of the former to provide it. If the employer has made adequate treatment available to the employee, he is not liable for other medical services secured by the latter.—*Totton v. Long Lake Lumber Company*, 97 P. (2d) 596 (Idaho, 1939).

Society Proceedings

COMING MEETINGS

American Medical Association, Cleveland, June 2-6. Dr. Olin West, 535 North Dearborn St., Chicago, Secretary.

American Association for the Study of Allergy, Cleveland, June 2-3. Dr. J. Harvey Black, 1405 Medical Arts Bldg., Dallas, Tex., Secretary. American Association for the Surgery of Trauma, Montreal and Montebello, Canada, May 29-31. Dr. Ralph G. Carothers, 409 Broadway, Cincinnati, Secretary.

American Association for Thoracic Surgery, Toronto, Canada, June 9-11. Dr. Richard H. Meade Jr., 2116 Pine St., Philadelphia, Secretary.

American Association of Genito-Urinary Surgeons, Hot Springs, Va., May 29-31. Dr. Charles C. Higgins, 2020 East 93d St., Cleveland, Secretary.

American Association of Medical Milk Commissions, Cleveland, June 1-2. Dr. Paul B. Cassidy, 2037 Pine St., Philadelphia, Secretary.

American Association on Mental Deficiency, Salt Lake City, June 20-24. Dr. E. Arthur Whitney, Washington Road, Elwyn, Pa., Secretary.

American Broncho-Esophageal Association, Cleveland, June 3. Dr. Paul H. Holinger, 1150 North State St., Chicago, Secretary.

American College of Chest Physicians, Cleveland, May 31-June 2. Dr. Paul H. Holinger, 500 North Dearborn St., Chicago, Secretary.

American Gynecological Society, Colorado Springs, May 26-28. Dr. Richard W. TeLinde, Johns Hopkins Hospital, Baltimore, Secretary.

American Heart Association, Cleveland, May 30-31. Dr. Howard B. Sprague, 50 West 50th Street, New York, Secretary.

American Laryngological Association, Atlantic City, May 28-30. Dr. Charles J. Imperatori, 108 East 38th St., New York, Secretary.

American Laryngological, Rhinological and Otolological Society, Los Angeles, June 16-18. Dr. C. Stewart Nash, 277 Alexander St., Rochester, N. Y., Secretary.

American Medical Women's Association, Cleveland, June 1-2. Dr. Etta Gray, 649 South Olive St., Los Angeles, Secretary.

American Neurological Association, Atlantic City, N. J., June 9-11. Dr. Henry A. Riley, 117 East 72d St., New York, Secretary.

American Ophthalmological Society, Hot Springs, Va., May 29-June 1. Dr. Eugene M. Blake, 303 Whitney Ave., New Haven, Conn., Secretary.

American Orthopedic Association, Toronto, Canada, June 9-12. Dr. Charles W. Peabody, 474 Fisher Bldg., Detroit, Secretary.

American Otological Society, Atlantic City, N. J., May 26-28. Dr. Isidore Friesner, 36 East 73d St., New York, Secretary.

American Physiotherapy Association, Asilomar, Calif., July 13-18. Miss Evelyn Anderson, Stanford University, Calif., Secretary.

American Proctologic Society, Cleveland, June 1-3. Dr. William H. Daniel, 1930 Wilshire Blvd., Los Angeles, Secretary.

American Radium Society, Cleveland, June 2-3. Dr. William E. Costolow, 1407 South Hope St., Los Angeles, Secretary.

American Rheumatism Association, Cleveland, June 2. Dr. A. R. Shands, Dupont Institute, Wilmington, Del., Secretary.

American Society of Clinical Pathologists, Cleveland, May 29-June 2. Dr. A. S. Giordano, 531 North Main St., South Bend, Ind., Secretary.

American Therapeutic Society, Cleveland, May 30-31. Dr. Oscar B. Hunter, 1835 Eye St. N.W., Washington, D. C., Secretary.

Association for Research in Ophthalmology, Cleveland, June 3. Dr. Conrad Berens, 35 East 70th Street, New York, Secretary.

Idaho State Medical Association, Sun Valley, June 18-21. Dr. F. B. Jeppesen, 105 North 8th St., Boise, Secretary.

Maine Medical Association, York Harbor, June 22-24. Dr. Frederick R. Carter, 22 Arsenal St., Portland, Secretary.

Medical Library Association, Ann Arbor, Mich., May 29-31. Miss Anna C. Holt, 25 Shattuck St., Boston, Secretary.

Minnesota State Medical Association, St. Paul, May 26-28. Dr. B. B. Souster, 493 Lowry Medical Arts Bldg., St. Paul, Secretary.

Montana Medical Association of, Great Falls, June 24-26. Dr. Thomas F. Walker, 206 Medical Arts Bldg., Great Falls, Secretary.

New Mexico Medical Society, Raton, May 26-28. Dr. L. B. Cohenour, 219 West Central Ave., Albuquerque, Secretary.

Ohio State Medical Association, Cleveland, June 3. Mr. C. S. Nelson, 79 East State St., Columbus, Executive Secretary.

Pacific Coast Oto-Ophthalmological Society, Los Angeles, May 26-29. Dr. C. Allen Dickey, 450 Sutter Street, San Francisco, Secretary.

Pacific Northwest Medical Association, Spokane, Wash., June 25-28. Dr. C. W. Countryman, 407 Riverside Ave., Spokane, Wash., Secretary.

Rhode Island Medical Society, Providence, May 28-29. Dr. Guy W. Wells, 124 Waterman St., Providence, Secretary.

Society of Surgeons of New Jersey, Plainfield, May 28. Dr. Walter B. Mount, 21 Plymouth St., Montclair, Secretary.

Utah State Medical Association, Salt Lake City, June 12-14. Dr. D. G. Edmunds, 610 McIntyre Bldg., Salt Lake City, Secretary.

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Thirteenth Annual Meeting, Held in Chicago, Nov. 1 and 2, 1940

The President, DR. CHARLES A. DOAN, Columbus, Ohio,
in the Chair

Effect of Heat and Cold on Gastric and Intestinal Motor and Secretory Activity

DR. J. DEWEY BISGARD, Omaha: In a series of patients kymographic records were made of gastric and intestinal tonus and peristalsis in response to the application of hot and cold packs to the abdominal wall and to the ingestion of hot and cold water. The motor activity was registered on indwelling inflated balloons connected to Miller-Abbott tubes. Records of the large intestine were obtained by threading balloons into the colon through colostomy openings. Applied externally, cold increased peristalsis and tonus of the stomach and bowel and caused a sharp rise in gastric acidity. Cold applied internally, by drinking ice water, produced the reverse effect. Heat applied externally decreased tonus and peristalsis, but when applied internally by drinking hot water it increased tonus and peristalsis.

Effect of Histaminase on Secretion and Motility of the Stomach

DR. HEINRICH NECHELES, Chicago: Experiments were performed on dogs with Pavlov pouches or with gastrotomies in which secretion was provoked by meals of meat or motility induced by injection of prostigmine methylsulfate. After control experiments histaminase was administered by injection or orally before and at varying intervals during the course of the experiment. Inhibition of secretion and motility was observed in some instances, while in the greater number of experiments no effect was noted. The inhibitory effect of histaminase does not seem to be a specific one due to destruction of histamine by that ferment, and the experimental data are interpreted to show that the occasional inhibitory effect is due to a nonspecific protein reaction.

Experimentally Produced Liver Damage and Gastric Acidity

DR. M. H. STREICHER, Chicago: The gastric juice obtained from dogs with Pavlov pouches by stimulation with histamine was studied before and after liver damage. The free and total acidities, the hydrogen ion concentration, the total base and chlorides were determined. The changes in blood proteins, non-protein nitrogen and the icterus index were observed. The gross and microscopic changes in the liver were studied.

Liver damage was produced in dogs by: (a) High voltage irradiation of the liver directly exposed at various intervals over a period of three years. The abdomen of each dog was opened under anesthesia with pentobarbital sodium, the viscera were blocked off from the liver by lead plates and the liver was exposed to forty-two minutes of high voltage radiation or the equivalent of three times the human cutaneous erythema dose. Each dog received 150 roentgens each minute for forty-two minutes. (b) Intragastric administration of carbon tetrachloride (1 cc. per 7 pounds [3.2 Kg.] given three times weekly) over a period of two to three years.

There was evidence that a disturbance occurred in the acid secretory mechanism of the stomach secondary to moderate or severe liver damage. Progressive liver damage depressed the acidity of the gastric juice. The gastric juice obtained (in this experiment) from the Pavlov pouch was apparently highly buffered. An attempt was made to study the nature of the buffers. Definite microscopic changes were noted in the livers of dogs exposed to radiation.

Acid-Base Equilibrium and Renal Function During Hypochloremia

DR. JOSEPH B. KIRSNER and KATHRYN KNOWLTON, Ph.D., Chicago: The relationship of hypochloremia to the rise in blood nonprotein nitrogen observed in pyloric stenosis and intestinal obstruction has long been a subject of interest. Experiments were conducted in dogs in which severe hypochloremia was induced by the intermittent removal of gastric contents through a gastric cannula. Dehydration was combated by the use of adequate quantities of chloride free water. The effects of this hypochloremia on the acid-base equilibrium were studied in detail. Urea clearance studies were carried out on 1 dog. The results indicate that severe hypochloremia is not followed by an appreciable rise in the blood urea nitrogen when large amounts of fluid are ingested. The renal function remained normal throughout, despite the reduction in blood chlorides.

Site of Absorption of Iron from the Gastro-intestinal Tract

DR. WILLIAM R. ARROWSMITH and VIRGINIA MINNICH, M.S., St. Louis: The intestinal tract of patients was obstructed at various levels by inflating a balloon attached to one of the openings on a Miller-Abbott double lumen tube. Soluble ferrous salts (4 mg. of elemental iron per kilogram of body weight) were given parenterally through the tube either proximal or distal to the obstruction; serum iron values were determined at intervals of about one hour during the subsequent six hour period. The data accumulated indicate that absorption occurs most readily in the stomach and duodenum, to a smaller degree in the jejunum and to an even lesser extent in the ileum. No satisfactory method has been devised for differentiating between absorption of iron from the stomach and the duodenum in patients. No evidence of absorption was noted when iron salts were given rectally.

DISCUSSION

DR. A. C. IVY, Chicago: The type of response obtained in experiments on the effect of hot and cold drinks on the rate of gastric evacuation is apparently not uniform and appears to be dependent on the state of tonus and motility of the portion of the alimentary tract being studied when the stimulus is being applied. If cold water inhibits gastric motility, regardless of its effect on the pyloric sphincter, the rate of evacuation of the stomach would be decreased, because, whether or not the stomach ejects material into the duodenum depends on the relationship of the pressure in the stomach to the pressure in the duodenum. If it is less in the stomach than in the duodenum

nothing will flow from the stomach. Dr. Todd's results on the effect of cold fluids on gastric evacuation could be explained by an increase in tonus of the stomach. In view of the contradictory results in the literature regarding the effect of hot and cold applications to the abdomen, I teach that the comfort of the patient should determine whether hot or cold applications are best. Few of the articles on histaminase report the use of adequate controls; the investigators have not inactivated the histaminase preparation or injected parenterally or into the duodenum the heat-inactivated material. When we try to ascertain if an enzyme is producing certain phenomena we always inactivate that enzyme with heat as a control. Research in this field is characterized by a failure to perform control tests with heat-inactivated material. Some investigators believe that bile salts may play a role in the absorption of iron from the intestine. I should be interested in seeing Dr. Arrowsmith go further in his well planned experiment and introduce iron into the ileum with bile salts to ascertain if the serum iron level might not be increased.

DR. WALTER L. PALMER, Chicago: Dr. Klein, working in our laboratories, has used what we consider to be large doses of histaminase—20 units given intravenously—and found a 50 per cent decrease in the volume of secretion of histamine without any effect on free acidity. It should be noted that animals were not made ill by this large dose of histaminase. Dr. Kirsner's study represents one aspect of a larger problem, i. e., the mechanism of alkalosis. His observation on the alkalosis of experimental hypochloremia is in accord with other observations he has made, namely that the major factor in alkalosis of any type is not renal injury but loss of chlorides and dehydration. Of interest is the fact that gastric secretion in patients with severe hypochloremia is not materially impaired.

DR. GRACE M. RORR, Rochester, Minn.: Dr. Horton and I obtained the greatest inhibition of the rise in gastric acidity by introduction of a specially prepared histaminase into the duodenum of normal trained human subjects thirty minutes before they were immersed in cold water or given histamine subcutaneously. One should bear in mind the fact that it is not always easy to compare the results which are seen in human beings and those observed in animals with Pavlov pouches. Since Dr. Ivy suggested the inactivation of the histaminase for better controlled experiments, we again repeated some of these observations this summer, using the same material which had been effective the year before. The observations were made with subcutaneous injections of 0.1 mg. of histamine. The first portion was introduced into the duodenum before the injection of histamine into the normal human subject, and the histaminase again produced an almost complete inhibition of the rise in gastric acidity expected from the injection of histamine. Some days later, when another portion was filtered and introduced into the duodenum as before, there was a moderate rise in gastric acidity from the injection of histamine. When the remaining portions were boiled on a water bath five and ten minutes respectively and introduced into the duodenum, the rise in gastric acidity was nearly that produced by the injection of histamine; when the boiled portions were filtered and introduced into the duodenum, the rise in gastric acidity was the same as that produced by the control injection of histamine alone.

DR. HOWARD L. ALT, Chicago: I have seen a number of patients with iron deficiency anemia who responded poorly or not at all to enteric coated ferrous sulfate. One patient who had had a gastric resection received 0.4 Gm. of enteric coated ferrous sulfate three times a day for six months with no response in the hemoglobin. When half the dose of ferrous sulfate was given in a syrup solution, the hemoglobin responded in the usual manner.

DR. J. DEWEY BISGARD, Omaha: Before starting this work we were aware, of course, of the various factors that influence motor activity, such as psychic and emotional factors, the contents of the stomach at the time of observation and the like. In an effort to control these factors all studies were done on the fasting stomach and were carried out only after conditioning the patients to the experimental procedure by repeated introductions of the Miller-Abbott tubes. The records did vary a good deal, but still there was a definite and consistent pattern. Among

experimental factors which may influence results and account for discrepancies is the thickness of the abdominal wall, as shown by a Japanese investigator. Working with rabbits, in which the wall of the stomach is near the surface, he showed that after the application of ice to the abdominal wall there was a decrease in peristaltic activity if the ice remained for some time, but when a small screen was placed between the skin and the ice so that there was less opportunity for rapid conduction of heat and therefore no chilling of the gastric wall there resulted an increase in peristaltic activity. Of course, the contents of the stomach make considerable difference in the response. Todd has shown that when milk and water enter the stomach at the same temperatures they cause entirely different peristaltic responses.

DR. HEINRICH NECHELES, Chicago: I used insulin or prostigmine methylsulfate to stimulate gastric motility. Histaminase was given intravenously, subcutaneously or into the stomach, and, as a control, only saline solution was given in the same volume as the histaminase solution. There was only one experiment in which suppression of gastric motility occurred, lasting for twenty-three minutes and then returning to normal. The same preparation used on another dog gave no response. There were toxic effects from certain preparations when given intravenously, intramuscularly or subcutaneously, as evidenced by a considerable and often prolonged drop of blood pressure. I did not do inactivation of the enzyme with heat for the following reason: I was trying to find a preparation of histaminase with a constant stimulating or depressing effect. I could not. Practically every tablet or ampule varied in effect. Since this made proper controls impossible, I did not inactivate the material. I believe we have definitely shown that the available commercial preparation of histaminase is inconstant in its biologic effects and that it may stimulate certain secretions of the gastrointestinal tract. In studying the clinical reports we have been struck by the fact that histaminase was least effective in those conditions for which a histamine-like substance is believed to be responsible. In other words, it seems that the effect of histaminase is not due to its enzyme content but to some impurities.

DR. JOSEPH B. KIRSNER, Chicago: Can dehydration be prevented by the administration of water alone in a patient with severe hypochloremia? I think not, because the body will not retain water when the chlorides are decreased. Furthermore, one cannot rely on clinical signs such as the urinary output to determine the presence or absence of dehydration. In one study done by McCance in which chloride deficiency was produced by diet and sweating, the body fluids were depleted by 38 per cent and the blood urea nitrogen rose to high levels. We have an experiment in man now in progress in which we are attempting to produce gradual depletion of chlorides and at the same time maintain an adequate intake of fluids with intravenous injections of dextrose and distilled water. It is too early to give the results, but the indications are that there will be no great rise in the blood urea nitrogen level if the depletion of chlorides is gradual. The removal of chloride by the Wangenstein tube is a rapid process. In the present study the gastric juice was removed for a period of only three hours each day. I think that, if similar conditions can be accomplished in man, a rise in blood urea nitrogen may occur but never to the extent of such high values as 100 to 125 mg. per hundred cubic centimeters.

Effect of Occlusion of Ureter on Experimental Hypertension

DRS. HARRY GOLDBLATT and JOSEPH R. KAHN, Cleveland: In 40 dogs, constriction of the main renal artery of one kidney was followed, almost invariably, by significant elevation of the systemic blood pressure which usually lasted two to six weeks. In 20 dogs in which one main renal artery was constricted and the ureter of the same kidney occluded, there was no elevation of blood pressure during a period of four weeks following the operation. In 5 animals with hypertension due to unilateral renal ischemia, occlusion of the ureter of the ischemic kidney caused the blood pressure to fall. These observations have special significance in cases of human hypertension associated with unilateral renal disease. Unilateral

nephrectomy may not be followed by a fall of blood pressure in such cases if the ureter is completely obstructed and the blood vessels are diseased.

A Substance in Kidneys Which Lowers Arterial Pressure in Hypertension

DRS. I. H. PAGE, O. M. HELMER, PH.D., K. G. KOHLSTAEDT, P. J. FOURS and G. F. KEMPF, Indianapolis: Harrison, Grollman and Williams and our group have come to the conclusion that normal kidneys contain a substance which reduces arterial pressure in both animals with experimental hypertension and in human hypertensive subjects. This substance has been extracted, and methods will be described for its preparation. When it is injected into hypertensive dogs and rats, the blood pressure falls little during the first days, but as the daily injections are continued the fall is accelerated. Usually after about five days the pressure may be at or near normal. If the blood pressure falls too rapidly the level of urea nitrogen in the blood may rise.

When the injections are discontinued, the arterial pressure slowly rises but may not regain its former level in some animals for many days or weeks. Many animals in which the malignant syndrome has appeared have been successfully treated.

Fourteen patients, 5 of whom exhibited the malignant syndrome, have been treated. Arterial pressure has fallen to levels near normal, and, when the injections have been received regularly, the lowered pressure has been maintained. Clinically the patients appeared improved.

Factors Contributing to the Development of Hypertension in Patients Suffering from Renal Disease

DRS. EDGAR A. HINES JR. and HOWARD H. LANDER, Rochester, Minn.: This article was published in THE JOURNAL, March 15, page 1050.

Response of the Blood Pressure to the Cold Pressor Test in Addison's Disease During Treatment with Desoxycorticosterone Acetate

GRACE M. ROTH, PH.D. and DRS. FRANCIS J. ROBINSON and RUSSELL M. WILDER, Rochester, Minn.: In the subjects of the present report, namely 10 patients with Addison's disease who were treated with desoxycorticosterone acetate, the response of the systolic and diastolic blood pressure to the cold pressor test and postural changes was studied. The period of treatment extended from thirteen days to nine months. Subcutaneous injections of desoxycorticosterone acetate ranging from 2.5 to 5 mg. daily were given, and in each of 2 patients implantations were made of 400 mg. In all 10 patients the levels of both the systolic and diastolic blood pressure were increased as well as the response to the cold pressor test. The increase of the systolic and diastolic blood pressure in response to the cold pressor test was striking and became greater as treatment was prolonged.

DISCUSSION

DR. ALF S. ALVING, Chicago: Two reasons based on experimental work may be advanced for sympathectomy in hypertensive patients. First, based on Dr. Goldblatt's work, it has been postulated by some who have advocated partial sympathectomy or splanchnicectomy that these procedures might result in an increased flow of blood through the kidney by relieving spasm of the arterioles of the kidney. Secondly, some investigators have experimentally produced neurogenic hypertension by sectioning the carotid sinus and modulator nerves; this hypertension can be relieved completely only by total sympathectomy. With these observations in mind we felt that the neurogenic factors in human hypertension could possibly be abolished and the disease benefited by total bilateral paravertebral sympathectomy. We have operated on seven patients. For our first subjects we chose patients with severe and almost hopeless hypertension. One, whose condition before operation was desperate, died two days after operation. Five have had a substantial reduction in blood pressure. None have been under observation longer than five months, so that we do not know whether or not any of the results are permanent. One patient has no reduction of blood pressure while she lies down, but in the erect position her blood pressure falls to 120 systolic and 80 diastolic.

Donated by

All these patients have some degree of postural hypotension and, for a month or so, have suffered from dizziness and fainting. In 1 patient we have evidence that a relaxation of the efferent arterioles occurred, as indicated by a significant diminution in the fraction of plasma water filtered and an increased flow of blood through the kidney. In 4 other patients there occurred either a diminution of renal blood flow after operation or no significant change in blood flow, as measured by the method of Dr. Homer Smith and his co-workers. It is obvious, therefore, from these studies that such a fall in blood pressure as occurs from operating on the sympathetic nervous system for hypertension is not necessarily accompanied by an increase in the flow of blood through the kidneys. We have found neither the cold pressor test nor the use of sodium amylal of value in predicting the postoperative results so far.

DR. EDGAR V. ALLEN, Rochester, Minn.: There are some questions for Dr. Page and his co-workers: Is this extract specific; that is, are the kidneys the only tissue whose extract favorably influences blood pressure; has he used as controls extracts made in a similar way of the spleen, muscles, liver and other tissues? The second question is relative to the possible bad side effects of repeated injections of renal extract. The third question is relative to whether or not the effect of treatment of the patient with renal extract is more beneficial than the use of some other substance, especially the use of potassium thiocyanate, which in many instances relieves the symptoms and reduces blood pressure. The fourth question is relative to the time at which it may be expected that this extract will be available for general clinical use.

DR. PAUL STARR, Chicago: Is there any evidence that the patients may become immune to the antipressor substances?

DR. EMMET B. BAY, Chicago: Is there any evidence of improvement in renal function in those cases of malignant hypertension in which Dr. Page used the extract?

DR. A. C. CORCORAN, Indianapolis: An example of the results in human beings suffering from hypertension is provided by the last patient discussed by Dr. Page, a patient with malignant hypertension in whom, under treatment, systolic pressure had decreased from 260 to 160 mm. of mercury. The renal blood flow on three occasions before treatment averaged about 140 cc. a minute, and the filtration fraction was approximately 0.2. Under treatment with extract, the filtration fraction fell to 0.17 and to 0.12 and is now about 0.16, while renal blood flow increased to 170 and 250 and is now maintained at about 225 cc. a minute. In another case of malignant hypertension, the filtration fraction was 0.34 in control observations and fell to 0.20 with treatment, while the renal blood flow at first fell from 450 cc. to about 350 cc. and is now about 450 cc. a minute. The filtration fraction is a measure of the fraction of plasma water removed by filtration under intraglomerular pressure. The reduction of the filtration fraction with a tendency to increased flow of blood in spite of decreased systemic pressure in these cases can be attributed only to relaxation of constricted glomerular efferent arterioles. The renal changes in patients with essential hypertension and in dogs with experimental hypertension are similar. On one occasion we injected into a normal dog renal extract equivalent to 1,500 Gm. of renal tissue. The renal blood flow doubled in the twenty-four hours after injection, while the filtration fraction fell from 0.28 to 0.15. Blood pressure fell slightly from 130 to 85 mm. of mercury. There were no untoward symptoms or pyrogenic reaction. The effect of these extracts on the kidney seems to be due to neutralization of the humoral renal pressor system.

DR. LOUIS N. KATZ, Chicago: That the kidney plays a specific role in neutralizing renal hypertension is suggested by the fact obtained in our laboratory that transplanting a kidney into hypertensive dogs and permitting it to necrose led to a drop in blood pressure to normal levels which, in some instances, outlasted the disappearance of the kidney for as long as several weeks. This result could not be obtained with transplantation of any other tissue we have used. It is not a nonspecific depressor action because transplanting kidneys into dogs with normal blood pressure has no effect. I did not hear Drs. Goldblatt and Kahn explain why ligation of the ureter of the

ischemic kidney caused the blood pressure to drop when a normal kidney was also present. On the basis of my results which show that the normal kidney tends to neutralize hypertension, is it not possible that the ureteral ligation, by stopping the activity of that kidney, causes the activity of the contralateral kidney to increase and thereby augments the latter's ability to neutralize hypertension?

DR. HEINRICH NECHLES, Chicago: I have observed dogs with essential hypertension. When these animals were put into shock and then infused with dog serum their hypertension returned, while in similar experiments on previously normal dogs the blood pressure could be brought beyond the shock level but not above the preshock level. The same has been seen in a few patients with hypertension who went into shock for one reason or another and were infused with pooled human serum; when they came out of shock their hypertension reappeared.

DR. GEORGE E. WAKERLIN, Chicago: Unquestionably, the amount of collateral circulation to the kidney is an important factor in determining the degree and persistence of the experimental hypertension. However, observations indicate that this is not the sole explanation, and I am inclined to the belief that extrarenal factors influence the character of the hypertension in the face of the same amount of renal ischemia. Most probably these extrarenal factors in the hypertensive dog are the same as those in the cases which Drs. Hines and Lander have discussed.

DR. HARRY GOLDBLATT, Cleveland: In answer to Dr. Katz, Dr. Kahn and I thought we had referred to the probable part played by the normal kidney in neutralizing or inhibiting the hypertensive effect of unilateral renal ischemia. We did not stress it because we do not know exactly how it acts. Whether this is the only mechanism involved when the artery is constricted and the ureter is occluded, and just exactly how it acts in these circumstances, we cannot state. We have suggested that an additional factor may be the failure of the hypothetic effective pressor substance to enter the systemic circulation in sufficient quantity to affect the blood pressure. We have repeated the work of Dr. Katz and his collaborators on the effect of the implantation of pieces of normal kidney under the skin of dogs with experimental hypertension due to renal ischemia. For our tests we used 7 animals which had had hypertension for years, the same number of animals used by Dr. Katz and his collaborators. Instead of using only 10 Gm. of tissue, as they did, we used as much as 30 Gm. Although they reported a fall in blood pressure in most of their animals, we found no significant effect on the blood pressure as a result of this procedure. As a possible explanation for the difference, we suggest the fact that in none of our animals did the wound open or break down or the liquefied material run out, whereas they reported that this almost invariably happened. It is probable that infection played a part or that hypertension had not yet become well established in their animals at the time of the test.

NOTE: Since making this comment at the meeting, we have performed 12 more subcutaneous implantations of renal tissue into hypertensive animals. In only 1 out of the 12 was there any effect. On the second day after the operation there was a large fluctuating mass at the site of the implantation. This was opened and proved to be an abscess. Within seventy-two hours after the evacuation of the pus the blood pressure had returned to its original high level.

DR. I. H. PAGE, Indianapolis: Only a few facts are known about the mechanism of action of this inhibitor substance, but these are not sufficient to enable one to decide whether the substance acts specifically to inhibit the angiotonic vasopressor system. The kidneys seem to be the chief source of it in the body. Some appears to be contained in muscle but a good deal less than in the kidneys. We cannot answer the question whether there are bad side effects. Local and sometimes febrile reactions occur, not unusually after injection of the material in some patients. We have not observed the type of vascular change observed by Winternitz in his studies on the production of hemorrhagic arteriolar necrosis. It will be recalled that

he used the so-called fraction D of Helmer and Page as the starting point for the preparation of his necrotizing substance and that the pressor and necrotizing materials tend to follow one another during fractionation. The effects of the inhibitor on arterial pressure in human beings seems to be more profound than those of potassium thiocyanate. That is to say, the blood pressure can be depressed to a greater degree. The clinical results in malignant hypertension are also more impressive. I do not intend to convey that I think thiocyanate of no value when employed by the method recommended by Barker. One can appreciate that 1,000 Gm. or more of whole kidney is a large amount. Experience has shown that the yields can usually be improved, and that is one of the problems which is facing us at present, that and the problem of converting a laboratory to a plant scale operation. I regret that I cannot tell you when this substance will be available for general clinical testing, and certainly until it has received that examination it cannot be accepted as a therapeutic agent. We have so far not seen any development of immunity. Somewhat against the idea is the fact that we are able to use our hypertensive dogs and rats over and over again in most cases without their becoming resistant to active extracts. The blood pressure in both malignant and essential hypertension is reduced by the extract, but the results in malignant hypertension are more dramatic, I suppose, because the symptoms and signs are more dramatic to start with. I described the partial restoration of vision, which is naturally impressive. Dr. Nechles asks whether a renin activator persists in the blood for any length of time. We have used plasma kept in the refrigerator for two to three days after being drawn without observing any noticeable decline in the activator content, but beyond that I do not know.

DR. EDGAR A. HINES JR., Rochester, Minn.: In a group of approximately 1,800 patients, with or without urologic disease, who returned to the clinic after twenty years, 45 per cent of those who gave a history of hypertension in one parent on their first visit had hypertension twenty years later, and 90 per cent of those who gave a history that both parents had hypertension showed hypertension twenty years later. Dr. Roth has shown a reproduction over a short period of time of what I have observed over a period of ten years in a group of persons who were originally hyperreactors and who eventually incurred clinical essential hypertension. These patients show increased hyperreactivity to the cold pressor test and more sustained high levels of blood pressure and hypertensive changes in the ocular fundi. With one exception, desoxycorticosterone acetate is the only substance that I know of which has been demonstrated to produce an increase in vascular hyperreactivity as measured by the cold pressor test. The single exception is the intravenous injection of calcium chloride. I call attention to this because there may be a relationship between inorganic ion balance and vascular hyperreactivity. I hope Dr. Roth and her associates will be able to elucidate the mechanism which produced the increase in vascular hyperreactivity in their patients because in it may be a clue to some of the things we do not understand concerning control of the circulation and blood pressure.

DR. GRACE M. ROTH, Rochester, Minn.: We did not have cold tests on these patients before they had Addison's disease. We have used this substance only a short time, and in many instances, but not in all, in which the blood pressure was elevated the clinical condition of the patient was improved. Furthermore, the number of patients we have observed has been small. We should like to call attention to the fact that by means of this crystalline substance high levels of blood pressure developed in patients who had previously had low blood pressure readings. Since this has occurred repeatedly and has been sustained over a period of nine months, it might be well in the treatment of patients with Addison's disease to keep in mind the possibility of the development of hypertension with more prolonged therapy.

Capillary Circulation in the Malarial Infected Monkey—A Cinematographic Study

MELVIN H. KNISELY, PH.D.; DR. WARREN K. STRATMAN-THOMAS and THEODORE S. ELIOT, PH.D., Chicago and Memphis, Tenn.: By transillumination with a quartz rod, arterioles, capillaries, sinusoids and venules have been studied in the omentum,

mesentery, striated and smooth muscle, intestinal villi, dura mater, pia mater, cerebral cortical surface, liver, lung, adrenal glands and spleen of "normal" amphibians and mammals.

Vessels of those organs in italics were studied in 5 *Macacus rhesus* monkeys infected with *P. knowlsi*. Pentobarbital sodium was the anesthetic used.

In normal animals (1) there is a normal rate of blood flow in the capillaries of each tissue for each physiologic state of the animal; (2) in arterioles and venules the flow is in concentric cylinders—streamlined; (3) most leukocytes are swept along in flowing blood; occasionally one rolls along endothelium; (4) normal erythrocytes are not fibrin coated, do not stick together or to endothelium and are not phagocytized in the spleen or liver.

A layer of fibrin or a fibrin-like substance is precipitated on knowlsi-parasitized erythrocytes. Coated erythrocytes do not stick to ordinary endothelium but do stick to one another, forming "clumps" which stick to and are instantly engulfed by hepatic phagocytes. Later, plasma viscosity increases, and phagocytosis of clumps slows down or may stop. Small clumps unite forming larger ones. Clumps and viscous plasma destroy streamline flows, increase the heart's work, reduce flow rates in all tissues below normal values.

Ordinary endothelium becomes sticky to solidly coated with leukocytes. Hence "leukopenia" in drawn blood. Terminal symptoms are manifestations of damage resulting from greatly slowed capillary circulation rates.

Etiology of the So-Called Side-Ache That Occurs in Normal Persons

DR. RICHARD B. CAPPS, Chicago: In spite of the frequent occurrence of side-ache little information is available concerning its characteristics or origin. This report is based on a study of 114 personally observed attacks in 55 different persons. The outstanding characteristics were found to be a constant relation to exertion, tendency to occur after eating and in cold weather, variable location in either the right or left upper quadrant and relief from bending over or local pressure. Previously proposed theories of origin are shown to be untenable. A new explanation is suggested that satisfies all requirements, namely, anoxemia of the diaphragmatic muscle.

Asymmetrical Cutaneous Lesions in Pellagra

DRS. WILLIAM BENNETT BEAN, RICHARD W. VILTER and TOM D. SPIES, Cincinnati: Fifteen pellagrins with an atypical distribution of their dermatitis were observed in the nutrition clinic at Birmingham, Ala., during the spring and summer of 1940. These included examples of unilateral lesions or those with marked asymmetry. In all but 2 of these patients we found disturbances which led to a decrease in the blood supply to the tissues involved or to an increase in local metabolism. These cases throw light on the nature of the underlying pathogenesis and are in agreement with the concept of a defect in cellular respiration.

Pantothenic Acid in Human Nutrition

HAROLD KRAHNKE, B.S., and DR. EDGAR S. GORDON, Madison, Wis.: Using the bacteriologic method of assay for pantothenic acid developed by Strong and his associates, we have studied the normal excretion rate in 12 healthy young medical students and found it to vary between 2.1 and 7.2 mg. daily with an average figure of 3.7 mg. In addition, responses to test doses of 10 mg. administered both by mouth and subcutaneously were studied, and the results, although too few to be conclusive, nevertheless justify the hope that a diagnostic test of deficiency may be developed on this basis. The role of pantothenic acid in both nervous and endocrine disorders was discussed with especial reference to the deficiency lesions of a degenerative nature in the brain and spinal cord in animals, and the adrenal cortical necrosis with hemorrhage which has been described in rats.

DISCUSSION

DR. TOM SPIES, Cincinnati: I admire the accuracy of this method but I do not think it can be applied by the practicing physician. Pantothenic acid was so named because it was presumed to be present everywhere. Apparently it is present in most foods. Nevertheless, in persons who have a nutritional

deficiency such as beriberi the blood level of pantothenic acid is only 50 per cent of that found in normal persons. We believe, therefore, that there is such a thing as a pantothenic acid deficiency in man even though we have not found any clinical sign pointing to a deficiency of this substance.

Effect of Depriving the Infant of Its Placental Blood During the First Week of Life

Q. B. DE MARSH, M.S.; W. F. WINDLE, PH.D., and DR. HOWARD L. ALT, Chicago: Infants whose umbilical cords were clamped immediately after birth had an average of 0.56 million fewer red cells per cubic millimeter and 2.6 Gm. less hemoglobin per hundred cubic centimeters during the first week of life than infants whose cords were not clamped until the placenta had separated from the uterus. Erythrocyte and hemoglobin values in infants within an hour after birth were much higher than in blood from the cord. Reticulocytosis during the first week of life was appreciably higher when the cord was clamped immediately than when clamping was delayed. Depriving the newborn infant of its placental blood by early clamping of the cord is equivalent to submitting the infant to a hemorrhage.

Storage and Transportation of Blood for Military Purposes

DRS. ELMER L. DEGOWIN, ROBERT C. HARDIN and E. D. PLASS, Iowa City: Sturdy, rubber-sealed transfusion flasks in commercial production were adapted to be almost completely filled with a blood-dextrose-citrate mixture, thus minimizing trauma to the erythrocytes. Flasks of blood were packed in ice and shipped by transport plane from Iowa City to Oakland, Calif., and return via United Air Lines (a distance of 3,539 miles). In bloods shipped, both fresh and after storage for fourteen days, the plasma hemoglobin increased only a few milligrams per hundred cubic centimeters. The blood mixtures were later transfused without untoward reactions. Similar experiments were performed in shipping bloods approximately 500 miles by hospital ambulances. It was found practical to pack ten flasks of blood and the necessary ice in 10 gallon milk cans surrounded by commercial insulating covers. This obviates the production of special equipment in a national emergency. An inexpensive, easily constructed refrigeration indicator was devised to be attached to each flask. The transfusion of dextrose-citrate plasma aspirated from stored blood produced recovery from surgical shock in patients.

DISCUSSION

DR. O. H. ROBERTSON, Chicago: My information on the transportation of preserved blood during the last world war was limited to the effect of carrying a few bottles by ambulance up to the advanced dressing stations. These bottles got a good deal of bumping, but the results of transfusion, given frequently by candle light in dugouts, were excellent. Of course it was not possible to follow the patients in most instances, but I suspect, in view of the authors' results, that reactions seldom occurred. One more point: transfusions of whole blood should not be discarded in favor of transfusions of plasma. There has been too much publicity on plasma transfusions, and although I realize the importance of plasma in temporary emergencies I still feel that in patients with grave exsanguination there is nothing that takes the place of the red blood cells. It was observed during the last war that the fluids of the blood could be restored with various substances, but, while the patients recovered so far as shock was concerned, secondary infection, if present, often persisted for a long time and was probably related to the low concentration of red blood cells present. Patients given transfusions of whole blood seemed to get along much better.

DR. MAURICE HARDGROVE, Milwaukee: The advantages of both whole blood and plasma transfusions are realized, but it is only fair to say that there is a similar agent which has the same effect as plasma, and that is blood serum. The Canadians have used concentrated blood serum in sufficiently large quantities to be satisfied that it is of value in shock. All of us who have worked with serum or plasma have seen cases in which the immediate use of either agent has been of value while the physician is waiting for a suitable donor for a transfusion of whole blood. Is there any reason why plasma should be superior to serum in the treatment of shock?

DR. WALTER M. SIMPSON, Dayton, Ohio: I should like to ask whether any experimental work has been done on the preservation of blood or serum or plasma in tin cans. I believe that such a cheap and simple method would be feasible. As regards the shipping of blood or serum or plasma, it would be a simple undertaking for those engaged in refrigeration research to develop a refrigerated truck in which the temperature could be kept at a constant level for the transportation of these materials for military use.

DR. HEINRICH NECHELES, Chicago: I should like to enter a plea for the use of serum instead of plasma. I have found that plasma with sodium citrate soon shows precipitates, and on standing for a few weeks or months the plasma is serum, i. e., plasma out of which the fibrin has precipitated and which is diluted with sodium citrate. I feel, therefore, that for emergencies or for shipment abroad it would be much simpler to use serum to begin with. This process of precipitation can be prolonged if the plasma is kept cold. With serum this is not necessary. If it is prepared adequately it can be kept at room temperature for indefinite periods and still will be clear. The question also comes up whether, when the plasma shows precipitate, this may not be due to contamination rather than to the precipitation of fibrinogen. I would not trust such a solution unless I could make certain of that point. Furthermore, if transfusions of plasma are given I understand that a filter must be used, which complicates the procedure and adds to the expense. With serum this is not necessary. I wonder also whether, in cases of extreme shock, the introduction of relatively large amounts of sodium citrate may not have some bad effect.

DR. EDGAR A. HINES JR., Rochester, Minn.: There is a refrigerant powder recently placed on the market which, when dissolved in water, will reduce the temperature of the water to any desired degree near freezing. I have experimented with it to some extent in carrying out the cold pressor test and I have found that if the container is properly insulated the water can be kept at near freezing temperature for several hours.

DR. ELMER L. DEGOWIN, Iowa City, Iowa: I would rather not become involved in the discussion about the relative merits of serum and plasma. Many institutions have been working with serum for years and have had good success, but it means that certain expensive equipment must be installed to handle large volumes of blood, and many laboratories are not so equipped. I doubt that there are enough centrifuges in the country to carry out the preparation of the quantity of blood needed. We did not use tin cans in transportation of the blood. These glass flasks are inexpensive, and an attempt is being made to get their cost down to such a point that the whole equipment can be thrown away after it has been used. The appearance of precipitate in plasma is admitted, and every one who has worked with it has encountered that difficulty. However, it is not serious, and there is some question as to whether it would do any harm if the plasma was injected without being filtered. We have given it without filtration apparently without reactions. Another thing Dr. Necheles may have observed is that apparently this precipitate, the nature of which is not definitely settled, tends to disappear if the plasma is stored at room temperature. We do not know what chemical reaction is involved.

Determination of Bile Acids in Blood and Urine

J. L. IRVIN, PH.D., and DRS. C. G. JOHNSTON and E. A. SHARP, Detroit: Methods previously proposed for the determination of bile acids in blood did not eliminate error due to interfering substances. The procedure employed in this work provides for hydrolysis of whole blood in order to split the proteins and the conjugated bile acids. Cholic, desoxycholic and hyodesoxycholic acids have been determined in the whole blood and urine of normal human subjects and in cases of hemolytic anemia and polycythemia after the administration of soluble whole bile. The implication is that a procedure for the determination of bile acids in the blood in obstructive jaundice and in hemolytic phenomena should aid materially in the clinical investigation of these conditions.

DISCUSSION

DR. E. A. SHARP, Detroit: The implications of these studies are that the amount of cholic acid and other bile constituents found in hemolytic blood disorders is about one tenth to one

twentieth greater than the amount which will hemolyze normal cells in vitro. Therefore, the future of the experiment is to determine whether bile constituents in the peripheral blood will explain hemolysis and the hemolytic aspects of anemia.

The Cephalin-Cholesterol Flocculation Test in Hepatic Disease

DR. DAVID H. ROSENBERG, Chicago: The results of the cephalin-cholesterol flocculation test are reported for a group of 155 selected persons. The test gave positive results in all cases of unquestionable and suspected hepatic disease and agreed more closely with the clinical observations than with other laboratory data, including the bromsulphalein and the hippuric acid tests. In 43 out of 72 patients with unsuspected hepatic disease, flocculation tests indicated liver damage. More careful histories and reexaminations, supplemented by the bromsulphalein or the hippuric acid test, provided confirmation. The test ran parallel with the clinical improvement following treatment. It is concluded that the flocculation test is a sensitive test of liver damage, possessing prognostic value and useful in differentiating parenchymatous from obstructive jaundice. Data indicate that mild and subclinical chronic hepatitis occurs more frequently than is generally appreciated and, unless specifically sought, may elude recognition.

DISCUSSION

DR. FREDERICK J. POHLE, Madison, Wis.: My associates and I have examined serum from 284 normal persons and have yet to find a false positive reaction; we have examined 455 hospital patients without evidence of hepatic disease and found 3.3 per cent false positive reactions. In 23 cases of cirrhosis of the liver the test gave positive results in 100 per cent; in 52 jaundiced patients with hepatitis or focal hepatic lesions the test gave positive results in 95 per cent and in 25 cases of obstructive jaundice in 70 per cent. These were cases of complete obstruction with secondary disturbance of the liver. We agree that the flocculation test is a sensitive means of determining hepatic function. The only conclusion we could not draw is that it is of value in the differential diagnosis between hepatogenous and obstructive jaundice.

DR. DAVID H. ROSENBERG, Chicago: In cases of obstructive jaundice, a positive flocculation reaction depends entirely on the amount of associated damage to the liver. In this series, with the exception of a single instance of long-standing obstructive jaundice associated with advanced biliary cirrhosis, the flocculation tests, when they gave positive results, revealed only slight flocculations. Thus, in the early diagnosis of jaundice a negative or slight flocculation reaction may be regarded as indicative of the obstructive type.

Microcinematographic Studies of Responses of Reticuloendothelial Cells to a "Marked Antigen"

DR. BEN C. HOUGHTON, Columbus, Ohio: When a purified azo-egg albumin, a distinctly red dye antigen, was injected intravenously in experimental animals an important series of cytophysiologic changes was observed. The dye antigen was readily ingested by the macrophages of the tissues and other cells of the reticuloendothelial system. After a period of digestion and dissolution of the visible antigen, these cells appeared to respond by an increased budding and shedding of the colorless peripheral cytoplasm. This process seemed to precede the development of specific antibodies. The present report deals with an in vitro study of the phenomenon observed by Sabin. Splenic macrophage "clasmatocytes" were isolated in cultures and treated with varying concentrations of the azo-egg albumin antigen of Heideberger. Time lapse motion pictures in color were taken daily during the experimental period. During the first three days, heavy concentrations of dye were observed in these cells, which became increasingly phagocytic. On the fifth day much of the dye had faded, and clear zones of peripheral cytoplasm began the process of budding. The colorless cytoplasm underwent separation and rapid dissolution. On the seventh and eighth days many large pale cells had reached a climax of this process and were to be seen surrounded by large areas of cytoplasmic fragments. Active motility had ceased, and the individual cells were surrounded by large groups of active small lymphocytes. This phenomenon appeared only in the treated cultures.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Infectious Mononucleosis Without Clinical Signs.—

Reyersbach and Lenert report an outbreak of an atypical form of infectious mononucleosis in which clinical symptoms and signs were entirely lacking. The epidemic (16 cases) spread slowly through a sanatorium having 108 children with rheumatic fever who were receiving convalescent care. The disease was discovered accidentally during one of the routine leukocyte counts taken every three or four weeks. The 108 children (only 3 Negroes) had no contact with other children, and each was permitted only two adult visitors every six weeks. The infection was introduced by a white girl aged 6½ years, admitted on Oct. 10, 1939, who had leukocytosis. Physical examination on entry was negative. The child had undergone tonsillectomy on Sept. 25, 1939, and it was thought that the blood picture was a peculiar postoperative reaction. After a month the stationary leukocytosis decreased gradually, becoming normal by the end of November. On November 27 a routine blood count revealed a similar condition in a girl aged 12½ years; physical examination gave negative results. Her leukocyte count remained elevated for two weeks, then decreased gradually and was normal after one month. During the next six months the disease developed in 14 more patients and was discovered by routine leukocyte counts. None of these children had symptoms or fever. Physical examinations were entirely negative. The characteristic finding in all these cases was a striking rise in the total leukocyte count, varying from 59,300 to 18,400 cells per cubic millimeter. Differential counts showed that this rise was due to the marked increase in mononuclear cells. The lymphocytes rose to a maximum of 90 per cent and were never lower than 71 per cent at the height of the disease. There was a relative decrease in polymorphonuclear cells. The results of the Paul-Bunnell test were negative for all 16 patients. The epidemic differs from others in its low infectivity. Only 1 boy contracted the infection, and no other cases developed either in his dormitory or in his recreational group. In view of the

marked variation in susceptibility of the same child at different times, it was impossible to determine the incubation period. The interval between introduction and the appearance of the second case was approximately forty-eight days. If the disease developed in the third and fourth patients as a result of their exposure to the second patient, the incubation period was sixteen to seventeen days. However, at the end of the epidemic there again was evidence to indicate that the incubation period was forty days or longer. No evidence was obtained to indicate that the virulence of infections of the upper part of the respiratory tract or of rheumatic fever was enhanced by the agent of infectious mononucleosis. In spite of the absence of clinical symptoms and positive physical manifestations, the condition they believe should be classified as infectious mononucleosis because of the characteristic blood picture and the infectious nature of the epidemic.

Essential Hypertension in Childhood.—Sobel cites 7 cases of so-called essential hypertension in children between 4 and 12 years of age. The definition of essential hypertension given by Fishberg as chronically elevated blood pressure not evolved from antecedent renal inflammatory disease or urinary obstruction is further narrowed to exclude such obvious causes as adrenal cortical carcinoma, pituitary basophilism, hyperthyroidism, rheumatic fever and increased intracranial pressure. Essential hypertension will be regarded as renal but not as nephritic hypertension. Present experimental and pathologic data indicate that reduction of renal blood flow is the main initiating etiologic factor in producing so-called essential hypertension. In none of the 7 children has there been any evidence of cardiac enlargement, cardiac decompensation, thickening and sclerosis of the arteries of the extremities or diminution in renal function. Every child had had a tonsillectomy prior to the hypertension. In addition to the routine history, physical and fundoscopic examination, urinalysis and chemical blood determinations the minimal requirements for an adequate study of so-called essential hypertension in childhood are (1) blood pressure determinations of parents and relatives, (2) blood pressure determination of the lower extremities, (3) an intravenous urogram and possibly a retrograde pyelogram, (4) the Fishberg concentration test, (5) the Addis count, (6) a urea clearance test, (7) a teleroentgenogram of the chest, (8) an electrocardiogram, (9) a basal metabolism reading, (10) a perirenal insufflation when indicated, (11) a determination of the response to sodium nitrite, sodium amylal and, if necessary, an intravenous injection of pentothal sodium, (12) consideration of the behavior of the blood pressure during sleep and (13) a study of the response to the cold pressor test. This routine is important for diagnosis, prognosis and treatment. Hypertension in the parents makes it much more likely that permanent hypertension will develop in the child sometime during its life. A child whose elevated blood pressure drops to a normal level but who reacts positively to the cold pressor test should be carefully watched for hypertension later in life. That such high blood pressures and elevations may occur temporarily during adolescence are normal and do not impair future health has yet to be proved. A recent follow-up study by Hines and Brown of an original group of apparently normal subjects studied with the cold pressor test disclosed that hypertension had developed in 38 per cent of the hyperreactors and in none of the normal reactors six years after the original study. Hyperreacting children (especially those with intermittent elevations) should be carefully watched for the development of permanent hypertension later in life. Intermittent excursions tend to become more frequent and denote incipient hypertension. With advancing years permanent hypertension, with its sequelae, may follow "harmless," transitory hypertension of childhood. Such elevations in a child or adult should no more be ignored than the intermittent excretion of sugar in the urine. As a working hypothesis the hypertensive state may be regarded as frequently having its origin in childhood.

Tonsillectomy and Poliomyelitis.—In trying to determine the relation of tonsillectomy and adenoidectomy to poliomyelitis Fischer and his co-workers studied the age, date of onset, type of poliomyelitis, presence or absence of tonsils, date of tonsillectomy and date of death of the 507 children from 3 to 12 years of age who were treated in Toronto during the 1937 epidemic

of poliomyelitis. Of the 507 children 231 had their tonsils and adenoids removed, the tonsils of 267 were still present and for 9 there were no data. There was no significant difference in the monthly incidence between the tonsillectomized and the non-tonsillectomized patients. There was an increase in cases in both groups during the last week in July when the epidemic began. Up to 6 years of age, children with intact tonsils were in the majority. After the age of 6, tonsillectomized children were in the majority. The bulbar form of poliomyelitis was significantly higher in the tonsillectomized (except in those who had their tonsils removed from two to six months before onset) than in the nontonsillectomized group, being 18.6 and 7.5 per cent, respectively. The nonparalytic form was slightly, but not significantly, greater in the group with tonsils. The difference in the proportion of the spinal forms was not significant. The major cause of death was respiratory failure resulting from involvement of the bulbar nuclei. The mortality (6.5 per cent) among the tonsillectomized children was higher than among the children with intact tonsils (1.5 per cent). Bulbar poliomyelitis was higher and the nonparalytic form lower among those tonsillectomized within a month of onset than among those operated on more than a month before the onset of poliomyelitis. Twelve cases in which poliomyelitis developed within a month of operation are reported. The poliomyelitis was bulbar in 7 of these cases. From information on the general incidence of tonsillectomy among school children it was possible to compute the incidence of poliomyelitis during the 1937 epidemic among recently tonsillectomized children. A higher incidence was observed among the recently tonsillectomized group than among other children. The frequent recent reports of the occurrence of poliomyelitis in recently tonsillectomized children supports this observation. The higher incidence of bulbar poliomyelitis among tonsillectomized children suggests the possibility that the tonsillopharyngeal area is one port of entry for the virus and that the tonsils and adenoids serve as a barrier. Therefore tonsillectomy and adenoidectomy had best be postponed while poliomyelitis is prevalent in a community.

Progesterone-like Action of Desoxycorticosterone Acetate in Women.—Hamblen and his co-workers studied

the possible progestational action of desoxycorticosterone acetate in two groups of women; one group of 5 women (average age 25 years) was characterized by the common symptom of secondary amenorrhea from three to nine months and the other group consisted of 3 women (average age 29 years) who received desoxycorticosterone preoperatively. A total of 196 individual determinations was made on alterations in urinary titers of 17-ketosteroids. The average daily values for different patients prior to therapy ranged from 7 to 225 international units and during therapy from 10 to 219 international units. The average daily value for the entire group was 63 international units prior to therapy and 57 international units during therapy. In a total of 156 individual determinations on sodium pregnandiol glucuronide none of the patients excreted pregnandiol complex prior to therapy. During therapy a total of 18 mg. of sodium pregnandiol glucuronide was recovered during three of the eight cycles investigated, an average recovery of 2.25 mg. per cycle. All 5 patients studied had estrogenic endometriums prior to therapy (three hypoestrogenic and two persistent estrogenic). All 5 patients had estrogenic endometriums at the conclusion of the various cycles of therapy. Bleeding followed therapy in four of the eight cycles studied. Untoward clinical responses

were minimal. Two patients experienced definite disturbances in water balance, which involved decreased urinary volume, generalized edema, sensation of thirst, slight acceleration of pulse and slight elevation in blood pressure.

Distribution of Pantothenic Acid in Certain Products of Natural Origin. T. H. Jukes, Davis, Calif.—p. 193.

Riboflavin Content of Fruits.—Lanford and her associates determined the riboflavin content of apples, bananas, grapefruit, oranges, pears and tomatoes and found that the mean content per hundred grams of the edible portions of the respective fruits was 4.3, 47.7, 20, 27.8, 19.8 and 37.3 mg. For canned grapefruit juice it was 11.8 mg. The citrus fruits (orange and grapefruit), banana and tomato appear richer in riboflavin than apples and pears. Considered with reference to the amounts presumably involved in average human nutrition, each hundred calory portion of citrus fruit or of banana contributes its full quota of riboflavin to the dietary, while each hundred calory portion of tomato contributes more, and that of pome fruit (apple or pear) contributes less.

Pylonephritis of Pregnancy.—Prather discusses three phases of pylonephritis of pregnancy: 1. Prior to the last few years, sterilization of the upper part of the urinary tract of such a patient was a rare occurrence. Urinary antiseptics

usually failed to produce the desired results, as with these medicaments or with simply a generous fluid intake and rest fever would subside and symptoms would improve, but the urine practically never became sterile. Likewise cystoscopic treatment was similarly effective. The ketogenic diet was not tolerated and mandelic acid, with its restriction of fluid, was not desirable for the acutely ill patient with pyelonephritis. The use of sulfanilamide for infections of the urinary tract during pregnancy was begun with some hesitancy. Its use in pregnant patients, as in the nonpregnant, gave three types of results: 1. Those whose urine becomes sterile during medication and continued sterile during the remainder of the pregnancy even though medication was discontinued; that is, cured. 2. Those whose urine becomes sterile while taking the drug but in whom an afebrile pyuria or bacilluria recurs some time during the remainder of the pregnancy. 3. Those whose urinary sediments are not favorably influenced by sulfanilamide. Of 50 patients with pyelonephritis during pregnancy, 33 were cured with sulfanilamide, the urine of 9 became sterile during medication but an afebrile pyuria recurred during the remainder of pregnancy, and the urinary sediment of 8 did not improve during medication. Forty-seven of the 50 patients went to term, 2 were delivered prematurely and the pregnancy of 1 was interrupted because of uterine fibroids. The babies of the treated patients appeared to suffer no adverse effects, 47 were alive and healthy at birth, 1 was lost when the pregnancy was interrupted, 1 was born with a meningococle, and the data on 1 were not available. Of 50 patients with postpartum infections of the urinary tract who had sulfanilamide medication, in only 1 of 20 instances in which constant drainage was used did the urinary sediment become sterile, and 24 of the 30 remaining patients in whom constant drainage was not necessary were cured. If the two groups are tabulated as a whole there were 50 per cent cures, indicating that sulfanilamide is most effective. The author investigated the problem of recurrent pyelonephritis associated with pregnancy by studying the records of 72 patients who had had pyelonephritis of pregnancy and who later returned to the hospital with one or more pregnancies. In approximately 65 per cent the subsequent pregnancy was normal. Seventeen of the 72 patients had a recurrent pyelonephritis in their subsequent pregnancy. Of 43 patients who were known to have sterile urine between pregnancies, 8 had pyelonephritis in their subsequent pregnancy. This is about nine times the normal incidence of pyelonephritis in pregnancy. Of 36 patients whose urines were still infected or unreported during the interval between pregnancies, 14 had pyelonephritis in the subsequent pregnancy. This is about twenty times the normal incidence of pyelonephritis in pregnancy. Of the 72 patients with pyelonephritis of pregnancy who returned later in another pregnancy, the succeeding pregnancies of only 9 were complicated by toxemia. Therefore the author does not think that pyelonephritis should be considered as a cause of toxemia. However, until a larger series is available it can be said that only these data indicate that pyelonephritis is not a cause of toxemia of pregnancy.

Healed Tuberculosis of Kidney.—Baggenstoss and Greene cite the 15 cases (13 men and 2 women) of healed or regressing tubercles of the kidney encountered at the Mayo Clinic during eighteen years. Nine of these healed military tubercles were found incidentally at necropsy and the remaining 6 instances were similar military tubercles with definite evidence of regression but slight microscopic evidence of activity. In none of the cases was there any clinical evidence of either renal or pulmonary tuberculosis. The authors believe that these 15 cases probably represent only a small proportion of the cases in which tubercle bacilli actually lodged in the kidney. It is likely that in a significant number of cases these small tubercles are overlooked at necropsy, especially when they are located beneath the surface of the renal cortex. It is also likely that the lesions may often not be typical and are not recorded as tuberculosis. Also tuberculous lesions may heal without leaving a trace. Although the evidence presented demonstrates that tuberculosis of the kidney does heal, the authors agree with those who believe that when renal tuberculosis reaches the stage at which it gives rise to symptoms and clinically demonstrable changes it rarely if ever heals.

Probably the two most important factors in the healing of the tuberculous renal lesions were the comparative fewness of the infecting organisms and high individual resistance. That bacilli in the blood were few is suggested by the small size of the lesions and by the fact that the lesions were single in all but 1 case, were found in only one kidney and in some instances the kidney, other than the lungs, was the only site of the involvement. That active resistance to the infection was present is indicated by the fact that in each of these cases healing also occurred of the tuberculous lesions in the lung, hilar lymph nodes, liver or spleen.

*Treatment of Pyogenically Infected Wounds by Topical Application of Powdered Sulfanilamide and Sulfanilamide-Allantoin Ointment: Preliminary Report. J. R. Veal and R. G. Klepser, Washington.—p. 61.

Familial Nature of Pinworm Infection.—Cram discusses the incidence of familial pinworm infection determined during four years by examining the members of a person's family who came to the parasite clinic. A total of 320 families (1,525 individuals) were studied. In 286 white families the incidence of pinworms found among the 860 children examined was twice as much as that among the 493 adults; respectively 72 and 36 per cent were positive as a result of 4,940 swab examinations. The respective percentages for the 114 children and 58 adults in 34 Negro families were 51 and 7. Among the 286 white families 4 had no children and of the 11 adults examined 5 were positive. In the white families multiple cases were the rule rather than the exception; in only 70 of the 286 families was the infection confined to a single case; in the remaining 216 families an average of 3.4 persons per family was positive. In slightly more than one half of the Negro families only a single case was found. Generally the incidence was lower in the Negro families than in the white families; the difference was especially marked in adults. This difference in familial extent in the two races conforms to differences in incidence found in the entire survey, which involved the examination of 4,000 persons of the general population of Washington, D. C. In 125 of the white families, all children who were examined were found positive. In the remaining families evidence of infection was found in more than one half of the children examined. All the adults in 49 families were infected. Therefore the quantitative evidence is that oxyuriasis is frequently a familial infection. This is of great importance in connection with therapy and prophylaxis. The frequency with which positive swabs were secured from infected individuals was 54 per cent of the swabs of white children and 53 per cent of Negro children, as compared with 47 and 43 per cent of infected white and Negro adults, respectively. These observations emphasize the necessity of multiple swab examinations in the diagnosis of oxyuriasis.

Powdered Sulfanilamide and Sulfanilamide-Allantoin Ointment for Pyogenic Wounds.—Veal and Klepser report the results of the topical application of powdered sulfanilamide to 140 pyogenic infections. The infections included operative wounds, burns, compound fractures, leg ulcers, decubitus ulcers and traumatic wounds. In practically all the infections there was a mixture of organisms; the most common invaders were streptococci, staphylococci, the colon group and diphtheroids. In some the growth of *Bacillus pyocyaneus* was extensive. Regardless of the various bacteria found sulfanilamide caused an immediate inhibition of growth as judged by smears, plated colony counts and gross appearance of the exudate. A single application of the drug was not sufficient to prevent revival of growth. Repeated daily doses caused a rapid decline in bacterial activity, and plated cultures showed a progressive diminution until about the eighth day, when they became practically sterile. As sulfanilamide seemed to retard healing it was decided to incorporate it into an ointment. Several attempts were made with inert bases. Finally an effective combination with allantoin was found (10 per cent sulfanil-

amide, 2 per cent allantoin, 0.5 per cent chlorobutanol and enough greaseless base for the desired consistency. The base used was a glycerinated stearic acid ointment with triethanolamine. In a number of cases the same ointment was used without including allantoin in the formula. Although the wounds healed and lacked the indolent phase characteristic of full strength sulfanilamide, the growth of granulation tissue was not as rapid or as freely bleeding as when the allantoin was used. The routine technic for the treatment of all pyogenic wounds now is careful and complete débridement of the wound, drainage of all pus pockets, removal of all necrotic and devitalized tissue and the application of a sufficient amount of pure sulfanilamide powder to cover the diseased tissue completely. A sterile gauze dressing is applied over the powder, and fresh sulfanilamide powder is applied daily until (from four to six days) the purulent exudate ceases and the infection is under control. The sulfanilamide-allantoin ointment is then substituted for the powdered sulfanilamide. It is applied daily and covered with a gauze or oiled silk dressing. The granulation tissue responds quickly; it loses its pale and anemic color within a few days and is red and healthy. The infection remains under control, and normal healing is reestablished. The method has proved highly effective in combating the pyogenic organisms which are commonly encountered. The action of the drug seems to be entirely local. Its effectiveness is apparently in proportion to its concentration. No constitutional toxic reactions were observed.

Pneumonia in Children.—Holmes and his colleagues studied the duration, mortality and incidence of complications of 1,000 consecutive cases of lobar pneumonia and bronchopneumonia in children less than 12 years of age who received

no specific therapy (serum or sulfapyridine). The series can be used as a control in comparing results of specific therapy. The records studied are of patients admitted to six pediatric services of the Philadelphia General Hospital from March 1, 1933 to Dec. 31, 1938. The extent of the study over several years precludes the factor of the yearly variation in the virulence of the causative organism. Of the 537 patients with lobar pneumonia, 82 were less than 2 years of age and 455 between 2 and 12 years. Conversely, 319 of those with bronchopneumonia were less than 2, and 144 were from 2 to 12 years of age. Lobar pneumonia was encountered more frequently in male than in female children; 320 males and 217 females and 249 boys and 214 girls in the bronchopneumonia series. There were 318 white and 219 Negro children in the lobar pneumonia group and respectively 235 and 228 in the bronchopneumonia group. The lowest incidence was observed during August and the highest during March and April. Almost as high an incidence prevailed during January, February and May. In 50 per cent of both lobar pneumonia and bronchopneumonia cases there was a definite history of an antecedent infection of the upper part of the respiratory tract. Fever was the most frequent symptom in both types, occurring in 94 per cent of the lobar and 90 per cent of the bronchopneumonia cases. A higher fever was encountered on admission in lobar pneumonia. Next to fever in frequency was cough. Chills, rapid breathing, chest and abdominal pain, gastrointestinal symptoms, vomiting and anorexia were other frequent symptoms. Acute suppurative otitis media prior to admission was infrequent in both groups, although it was four times as common in bronchopneumonia as in lobar pneumonia. During hospitalization, cyanosis, abdominal distention, meningism and convulsions were observed. The day of onset was ascertained with any degree of accuracy in only 504 of the 537 cases of lobar pneumonia. The average duration of its acute phase computed from the time of onset to the time a normal temperature was maintained was five and one-tenth days. In the bronchopneumonia group the average duration in 421 cases was twelve and a half days. There were 124 errors among the 1,000 primary diagnoses; pharyngitis, acute bronchitis, influenza and acute tonsillitis accounted for 74, meningitis for 15 and gastrointestinal disorders for 13 and appendicitis, tuberculosis, pyelitis, empyema and tetany for some of the other errors. Acute suppurative otitis media was the most frequently encountered complication. It developed in a total of 278, or 27.8 per cent, of the cases; its incidence in bronchopneumonia was 38 per cent and in lobar pneumonia 18 per cent. Empyema occurred in 34 of the 1,000 cases. Two of these patients died before empyema was discovered. There were no mortalities among the remaining 32 cases. There were only 22 other complications: abscesses, meningitis, purpura. There were a total of 88 deaths among the 1,000 patients; only 7 of these occurred among the lobar pneumonia patients. Seventy of the 81 deaths in the bronchopneumonia group were of children less than 2 years of age; 28 of these 70 deaths occurred during the first six months of life. This demonstrates the high mortality from bronchopneumonia during infancy. Essentially, treatment of the 1,000 patients consisted in good nursing care with minimal disturbance to the patient, maintenance of fluid intake, prevention of cross infection and blood transfusions and oxygen when indicated. Drugs, enemas, tepid sponge baths and the like were not used as a routine but rather for the relief of special symptoms: severe cough, restlessness, delirium, abdominal distention and continued high fever. It is hoped that sulfapyridine or allied chemicals will be valuable in reducing the high mortality from bronchopneumonia.

Ariboflavinosis and Ocular Changes.—Sydenstricker and his colleagues state that their 120 patients with ariboflavinosis experienced rapid symptomatic improvement following riboflavin therapy. They observed that photophobia may be relieved after seventy-two hours of treatment; dim distant vision and twilight blindness may be cured in the same time. Mydriasis and defects in accommodation disappear concurrently. Dysphagia, gastric discomfort and general malaise have seldom persisted after the third day of treatment. Glossitis is the first anatomic lesion to show changes; usually the tongue is restored to normal color and texture by the third day. Corneal vessels respond almost as rapidly. By the fourth day of treatment there is obvious emptying of the smaller capillary channels and interruption of the flow of blood in the larger ones. In early cases all invading capillaries may be empty by this time. In patients with severe keratitis maximal improvement occurs during the second week of treatment; by then all capillaries are empty. Large vessels are not obliterated after as long as a year, though they diminish in size. The shortest time for the complete disappearance of subepithelial capillaries has been ten months. The amount of riboflavin required for satisfactory improvement depends on the adequacy of the diet and the ability of the patient to extract and utilize riboflavin from natural sources. Under experimental conditions with a diet poor in all vitamins 5 mg. of

riboflavin daily by mouth has given rapid cure. In the presence of gastric achlorhydria, diarrhea or severe hepatic disease from 10 to 15 mg. daily may be required. In cases of severe polyavitaminosis with vomiting and diarrhea, from 10 to 15 mg. of sodium riboflavin given intravenously may be required. Under uncontrolled conditions with a nearly adequate diet, 3 mg. daily is adequate for the cure and maintenance of most patients.

Hypoproteinemia in Surgical Patients.—Casten and Bodenheimer point out that from clinical and experimental evidence one must conclude that there is undoubtedly a specific mechanism or organ which controls the formation of serum proteins. This is of great importance in therapy, for if this mechanism or organ is impaired it is obviously futile to administer proteins which cannot be utilized to regenerate serum proteins. There is some evidence which indicates that the liver is the regenerating site. Edema is a result of hypoproteinemia and it is attributable to alterations in the mechanics of fluid distribution between the vascular and the extravascular spaces which are caused by a decrease in the colloidal osmotic pressure of the blood induced by a deficiency of the serum albumin. Many other factors may also influence this edema. Among them are tissue elasticity, water balance and the character and distribution of the electrolytes of the body fluids. Almost all the clinical manifestations of hypoproteinemia (peripheral edema, pulmonary edema and disturbances in gastrointestinal motility and wound healing) can be explained on the basis of disturbances in fluid distribution. Treatment is not always satisfactory, as the exact mechanism responsible for serum protein production is not known. Since the liver plays a definite and important role, treatment should be directed toward protecting and sustaining this organ. A high protein and carbohydrate intake is essential. Substitution therapy, whole blood or plasma transfusions, parenteral administration of amino acids or orojunal feeding of amino acids has had some success. In the authors' experience massive transfusions of plasma have provoked the greatest and most sustained rise in the serum proteins. The treatment of hypoproteinemia should be prophylactic. All patients about to undergo serious operative procedures should be carefully studied for disturbances in serum proteins, vitamins and fluids. If depletion of serum proteins is present the operation should, if possible, be postponed until the concentration is normal; frequently a high protein diet will suffice. If the necessary food elements are not absorbed when administered by mouth, other methods must be instituted. It is fortunate that many, if not most, surgical patients in whom hypoproteinemia develops exhibit no serious defect in the regeneration of serum proteins. The deficiency is usually amenable to treatment, and consequently the impairment in the mechanism of protein regeneration is slight. Malnutrition may affect the liver and impair its ability to synthesize serum proteins. Probably the restoration of the nutritional state to normal remedies this disability; frequently the proper administration of protein does replenish the serum

proteins and overcomes hypoproteinemia and its concomitant manifestations. In cases resistant to protein therapy, attention must be given to the liver. There is ample evidence that a high protein and carbohydrate intake is essential to protect the liver from damage by anesthetic agents or other noxious substances. This should guide the preoperative and postoperative care of patients and it may prevent hypoproteinemia from developing. Large amounts of intravenous dextrose in a 10 per cent solution in distilled water and a high protein diet by mouth or through an indwelling tube is the best means of preparing the liver for the shock of surgery or treating it when it has been damaged.

Clinical Value of Serum Amylase Test.—Lewison discusses 1,500 serum amylase studies in 900 representative patients in an effort to correlate the facts established by experimental investigation with the clinical factors observed in health and disease; to point out, if possible, the pathologic conditions in which the serum amylase test is of value, to determine its limits of utility and to caution against its sources of error. The method employed in the investigation (McClure, Wetmore and Reynolds, 1921) is based on the determination of the reducing sugar formed in the enzymatic hydrolysis of starch by a modification of the Folin Wu technic. In the preparation of the reagents and the analytic procedure the standards employed by Somogyi (1938) were observed. Although the analytic procedure employed is open to much the same criticism applied to all sugar reduction methods, practical experience under carefully controlled conditions with 1,500 serum amylase determinations has minimized the sources of error and the author believes the reliable nature of the results themselves is justified. Their interpretation and application to clinical conditions remain a matter of continued correlated study and medical judgment. Some of the diseases studied were appendicitis, cardiovascular, diabetic, gynecologic, genitourinary, neoplastic, rectal, infectious, gastrointestinal and thyroid. The author's conclusions are that: 1. Age, sex, diet, vitamin deficiency and starvation have practically no effect on serum amylase values. 2. Normal serum amylase levels ranged within constant limits when determined by a reliable method. 3. Because of the indiscriminate chemical composition and enzyme concentration in urine, feces and duodenal contents, amylase activity under such conditions is less uniform and diagnostically less trustworthy. 4. Ninety-four per cent of 720 patients having clinical conditions other than mumps or diseases of the biliary system had normal serum amylase values. 5. Patients with mumps had elevated amylase levels. 6. Patients with hepatic disease, regardless of kind, often had depressed amylase activity. 7. Deviation from normal occurred infrequently in diseases other than pancreatitis. The range of the deviation was rather restricted and not a source of diagnostic confusion. 8. A prompt and significant rise in serum amylase activity occurred in 4 cases of acute pancreatitis in which the diagnosis was confirmed and in 6 similar cases in which the diagnosis was presumptive. The amylase elevation reached its peak within the first forty-eight hours of the disease and usually returned to normal several days thereafter. 9. The determination in this disease is a most helpful and reliable diagnostic aid, particularly if the pancreatitis is to be treated conservatively.

Pectin for Wound Treatment.—Tompkins and his associates state that experimental work undertaken to explain the excellent results obtained with the apple diet and a pectin agar preparation (nickel pectin) in diarrhea of infants demonstrated that the pectin being used had bactericidal action under certain conditions. The possible therapeutic action of pectin solutions in the treatment of infected wounds was speculated on, and clinical evidence has accumulated to show that other pectins as well as the nickel pectin mixture have definite value in the treatment of wounds. Pectin powder is used in aqueous solutions in percentages which vary according to the case to be treated. Solutions ranging from 2 per cent (on the basis of 100 grade pectin) to as high as a thick paste of 10 per cent have been used. Solutions of pectin may become contaminated with fungi and, to prevent this, aqueous merthiolate was added to make a dilution of 1:200,000. This not only prevented growth of fungi but enhanced the bactericidal effect of the solutions and yet was dilute enough so that it was not toxic to tissue. Sterile

gauze dressings are saturated with the pectin solution, or the solution is applied directly to the lesions as needed. The dressings are changed as often as necessary to keep them moist. By using petrolatum gauze, oiled silk, heavy waxed paper or parafilm over the pectin dressings with a dry dressing over that, evaporation (which is excessive) is reduced to a minimum. During three years the authors treated 75 patients by this method. The series included 25 decubitus and trophic ulcers, 23 chronic discharging wounds, 19 operative wounds with drainage or secondary infection, 5 superficial wound infections and 3 traumatic wounds. Fifty-seven of these were treated with the nickel pectin solution and 18 with nickel-free pectin solution. No essential difference was observed in the results obtained in the two groups. The pectin dressings brought about a prompt visible change in the wound. The wound takes on a healthy appearance and fills in from the bottom with rapid formation of granulation tissue. This new tissue is of a smooth bright red type with a healthy glistening sheen, is firm and shows vigorous growth. The bactericidal effect of the pectin, merthiolate and the nickel when present appears to be only a part of the total therapeutic action. A considerable portion of the curative effect may be due to the hygroscopic property of pectin solutions which results in the decrease of edema in the granulations and leads to healthy wound healing. The granulation tissue which forms is actively growing and apparently not edematous and seems to rid itself of the effects of the infecting bacteria. The mechanical removal of organisms, pus and serum, with change of dressings, is probably also of some benefit. The acidity of the material does not seem to cause any irritation to tissue. On the contrary, the pectin dressings to the various types of lesions, according to patients, decreases the discomfort, particularly of infected operative wounds. Objectionable odors are absent. This is especially noteworthy in cases of osteomyelitis. The authors do not believe that the pectin has any direct influence on epithelization; in fact, pectin may inhibit this stage of healing. Accordingly, when a wound is clean and has filled to the desired degree, other medications are used to keep the lesion clean during epithelization. Except for cases of osteomyelitis there are no comparable series to serve as controls. However, the factor of case differences would not permit definite comparisons. Nevertheless the results in most of the 75 cases exceeded the usual expectations, and in many instances wounds that had been treated by the customary measures with no success showed prompt response to the pectin therapy. Results were good or excellent in practically every case. One superficial burn case and 1 case of impetigo failed to respond, as did a tuberculous nephrectomy wound in which sinuses continued to develop. In the cases of osteomyelitis the healing time following sequestrectomies was reduced by about one fourth of that required under other methods of treatment. These results have been confirmed by Thomson, who reports the use of 2 per cent pectin solutions for old infected burns, pressure sores, infected soft tissue wounds, osteomyelitis and infected compound fractures.

Advances in Treatment of Cancer with Radiation. C. L. Martin, Dallas, Texas.—p. 41.

*Radiation Therapy in Treatment of Infection. F. B. Bogart, Chattanooga.—p. 48.

Prolonged Labor. E. F. Buchner Jr., Chattanooga.—p. 61.

Radiation Therapy in Treatment of Infection.—Bogart obtained satisfactory results with irradiation in 83 per cent of 240 cases of inflammatory lesions. The types of lesions treated were adenitis, carbuncle, cellulitis, furunculosis, erysipelas, herpes zoster and simplex, chronic otitis media, sinusitis, infected salivary glands, gas bacillus infection and others. Staphylococcal infections generally give better results than streptococcal infections. For acute inflammatory lesions that are treated early, from 75 to 100 roentgens is given over the area on three successive days. When treatment is delayed until areas of necrosis or frank suppuration have occurred, doses of from 50 to 100 roentgens are used daily for two or three days and then at intervals of two or three days until a total of five treatments have been given. In chronic inflammatory lesions from 100 to 150 roentgens is given weekly or biweekly for from six to twelve weeks. For blastomycosis it may be

best to give from 300 to 400 roentgens and to repeat it at intervals of two or three weeks for three or four doses. Approximately two thirds of the average adult dose is used for children. The kilovolts and filtration are decided by the depth of the lesion. When from 85 to 100 kilovolts is used, from 1 to 2 mm. of aluminum filtration is sufficient. When 140 kilovolts is used, from 4 to 6 mm. of aluminum filtration is used. When the lesion is deep seated, 200 kilovolts is used with a filtration of from 0.5 to 1 mm. of copper and 1 mm. of aluminum. Some filtration should always be used.

Pulmonary Embolism.—Westdahl summarizes the important data of 247 cases of pulmonary embolism, of which 166 were medical, 80 postoperative or post-traumatic and 1 occurred post partum. Of the 138 nonsurgical cases that proved fatal, necropsy in 128 was performed; 56 of the 64 fatal cases with a surgical background were also studied post mortem. The 1 obstetric patient recovered. The diagnosis in all the cases in which recovery occurred was made by the presence of one or more episodes of sudden localized chest pain and an otherwise unexplained blood streaked sputum. The fatal medical cases not verified by necropsy were also diagnosed by these symptoms. The majority of postoperative patients died suddenly or rapidly after shock and signs and symptoms referable to the chest unexplained on any other basis. Two explanations for the high percentage of cases not diagnosed clinically are that the majority

Antiseptic Snuffs.—Delafield and his associates studied the effect of three antiseptic snuffs (proflavin, penicillin and sulfathiazole) in 20 subjects. The following tentative suggestions seem apparent: 1. An antiseptic snuff containing sulfathiazole or penicillin may lessen the frequency of effective invasion of the nose by bacteria or the nasopharynx through the nose. It may therefore prove useful as a prophylactic against bacterial infections of the upper part of the respiratory tract and perhaps against cerebrospinal meningitis. On the latter point there is no direct evidence except that sulfanilamide compounds are active against the meningococcus. The method seems worthy of trial. 2. There is no evidence that it will prevent or cure the common infectious cold. It may favorably affect the course of a cold by preventing secondary bacterial infection. 3. It may prove effective in curing nasal carriers of staphylococci or in reducing the number of vegetative organisms, so that the carrier becomes a less dangerous source of infection to others. 4. It seems desirable to test its possible usefulness in the treatment of nasal carriers of diphtheria bacilli, as the diphtheroids disappeared shortly after treatment was started. 5. How far it will affect other nasal pathogenic organisms there is as yet no evidence. So far the authors have not succeeded in freeing the noses of carriers completely from staphylococci. They have no data as to what happens after treatment with sulfathiazole snuff is stopped. It seems probable that treatment would have to be prolonged to effect any permanent cure and that in cases in which organisms are vegetating in deep crypts or in any of the nasal sinuses an antiseptic snuff would do no more than hold in check the surface colonization. The dispersion of the antiseptic snuff through the nasal passages will probably be similar to that of inhaled bacteria.

Prophylaxis of Throat Infection.—King discusses the need of some simple method of prophylaxis against infections of the upper part of the respiratory tract under the present conditions of overcrowding in air raid shelters. The method must be susceptible of being easily applied to large numbers of people. With the object of determining the value of the antiseptic throat spray a 15 to 20 per cent solution of sodium hypochlorite was chosen. Two groups living and working under identical conditions were selected for study. Each morning the group chosen for treatment was subjected to a throat spray until the time of its departure from the establishment some five weeks after joining. During these five weeks the incidence of sickness occurring in the treated group was greatly diminished. The number of patients requiring hospitalization during this period, as well as those receiving ambulant treatment, was reduced by half in the treated as compared with the untreated group. The diminution was due to the decreased incidence of acute and subacute throat infections (streptococcic tonsillitis and pharyngitis). The incidence, severity and duration of common colds (acute coryza) was more or less similar in members of the two groups. This suggests that the prophylactic treatment failed to attenuate the virulence of the infecting organisms in those cases in which they were not primarily

destroyed. The favorable results indicate that the antiseptic throat spray is a justifiable prophylactic measure against such common winter ailments as acute and subacute streptococcic throat infections and influenza.

Pulmonary Fat Embolism.—Robb-Smith discusses symptoms of pulmonary fat embolism on the basis of a postmortem study of 115 cases encountered in 789 consecutive accident cases. There was no injury to bone in 12 cases; 5 of these showed gross pulmonary fat embolism and in 6 it was regarded as a significant factor in the fatal outcome. In the 33 cases of skull fracture only 6 showed gross embolism and in 10 there was no embolism. In only 2 was the embolism believed to be important, as the majority had suffered severe cerebral injury. Of 70 cases of other fractures 8 showed no fat emboli, in 30 it was advanced and in 21 it was regarded as the major factor in death. Thus fat emboli were not found in 22, were severe in 41 and were regarded as a major factor in 29. The study demonstrates that it is possible to diagnose the condition which is usually regarded as chimerical. Whether the clinical conditions which follow injuries are due to shock or to fat embolism it must be borne in mind that the two may occur and are distinct, although they can show superficial resemblances. The possibility that fat embolism may follow severe concussion has been recognized for seventy years, yet as far as the author knows it has never been considered a factor following explosions. He suggests that the term "blast injuries" be abandoned in favor of concussion. Pulmonary concussion gives an idea of the pathogenesis and therefore of the rationale of treatment irrespective of the physical agent inducing it. It is conceivable that in injuries due to a bomb explosion the pulmonary parenchymatous hemorrhages induced by the concussion so alter the pulmonary arterial pressure as to produce death in a manner similar to pulmonary embolism. The author thinks that the pulmonary symptoms in bombed cases may be a combination of pulmonary concussion and fat embolism and hopes that pathologists will keep this possibility in mind when making postmortem studies. Should it prove true it may modify treatment. The general procedure in pulmonary concussion and fat embolism is essentially similar, but the effects of fat embolism are progressive and if a specific therapy should be found it would improve the outlook. Symptoms of pulmonary fat embolism arising from injuries come on after a symptom-free interval varying from a few hours to several days. The patient becomes dyspneic, pale, cyanosed and restless and, with little coughing, brings up frothy sputum which may be blood stained. Fat emboli in the systemic circulation may produce purpura or cerebral symptoms (stupor, fits or palsies). The blood pressure does not fall. Early immobilization of injured parts is the most important prophylactic measure. Anoxemia should be relieved with oxygen. Morphine should be avoided. Transfusions of blood or plasma should be withheld when symptoms of fat embolism have developed.

Hereditary Familial Purpura Simplex.—Davis adds sixteen families with purpura simplex to the eleven previously reported. Purpura occurred in only one generation in nine of the families, in two generations in twelve, in three generations in five and in one family in four generations. The twenty-seven families now include 88 members with spontaneous skin ecchymoses, of whom 84 were females; the 4 males came from four different families. The 88 cases comprise: 79 with purpura simplex, 4 with Schönlein purpura, 2 with Schönlein-Henoch purpura, 2 in different families who bruised on trivial injury (both suffered from active rheumatoid arthritis) and 1 with pseudohemophilia. Other abnormal hemorrhages were almost completely absent in purpuric members and their relations. In two of the families familial telangiectasia was a feature. Of the 88 persons, 23 gave a history of rheumatic fever, 8 of rheumatoid arthritis, 15 of some other form of arthritis and the others severe fibrositis. In some families the hereditary transmission can be explained on the basis of a dominant gene with partial sex limitation.

Sulfanilamide Locally for Prevention and Treatment of Gas Gangrene.—Bonnin and Fenner recommend a procedure for the treatment of war wounds which is based on their experimental work on guinea pigs whose inflicted contused wounds were treated locally with sulfanilamide powder either before or after the wounds were infected with cultures of *Clostridium welchii*, septic and oedematous, *Staphylococcus aureus*, *Streptococcus pyogenes* and mixed organisms. It is suggested that about 20 Gm. of sulfanilamide (probably in tablets or as compressed granules) be supplied each soldier. This sulfanilamide should be poured into a wound immediately after injury, either by the soldier himself or by a companion, and the first field dressing should then be applied in the usual way. On the soldier's arrival at the casualty clearing station the wound should be excised and again packed with sulfanilamide, whether primary closure is attempted or not. For the local application of sulfanilamide by medical officers, various methods may be used, including insufflation of the powder or the placing of solid pencils of the compressed powder along bullet tracks. For a more rapid rise in the concentration of sulfanilamide in the blood, oral administration of one of the sulfonamides may be advisable at an early stage. The issue of four tablets of sulfapyridine to each soldier would facilitate early administration. Whether it will be possible after excision to close wounds locally treated with sulfanilamide will have to be determined by experience. Provided the wounds are filled with sulfanilamide before closure, the treatment may be safe. This would represent a great advance, for primary closure and union by first intention remain the surgical ideal. If the wounds are left open, repeated local treatment, as used by Levaditi, may be employed. At the Mayo Clinic irrigation with a 0.5 per cent solution and a paste have been used for the purpose. The authors suggest that, if the Winnett-Orr closed plaster treatment of open wounds is used, it should be modified by packing the wound with sulfanilamide before the cast is applied. This will delay bacterial growth and may prevent the early pyrexia which must represent a period of infection and invasion by pathogenic organisms with resulting tissue damage. The authors' experiments suggest that the immediate local use of sulfanilamide prophylactically in all wounds may go far toward preventing bacterial growth and tissue invasion. The effects on pathogenic bacteria of local treatment by other sulfonamides must be studied.

Early Diagnosis of Tuberculosis of Knee.—According to Dubau and Bolot, detection of primary tuberculosis of the knee is often a difficult matter, in which diagnostic certainty is afforded only by the laboratory demonstration of the tubercle bacillus. Synovial biopsy may become necessary. The difficulty of diagnosis is illustrated by the fact that 37 out of 106 cases diagnosed as free from tuberculosis of the knee had to be observed for months and even for years to establish the diagnosis. (The value of early diagnosis lies in prompt immobilization of the tuberculous knee.) In 37 of these cases associated tuberculous lesions were found before or after articular localization. Of these, twenty were single (pulmonary tuberculosis six times, Pott's disease four times) and fifteen were multiple lesions. Skeletal lesions seen in the roentgenogram consist in decalcification and possess practically no differential value. Likewise, bone degeneration appears too late to aid diagnosis. It is only in the soft tissues that roentgenoscopy is revelatory. Here edema and infiltration present a dirty opaqueness, especially when both knees are roentgenoscopically contrasted. The appearance of the synovial cul-de-sac in the roentgenogram is an important though not a conclusive sign. In the early stages of the disease, this cul-de-sac is empty and only its parietal outline is traceable in the film. The identification of the tubercle bacillus may be done directly from the intra-articular fluid, or the synovial wall, or culturally or by inoculation. The first is rarely positive. Macroscopically, synovial biopsy is of little value. Its microscopic evidence is greater, but by no means pathognomonic. The bacteriologic test effected by inoculating guinea pigs was positive in eleven out of thirteen biopsies performed and negative in the remaining two. In 8 cases both microscopic and bacteriologic tests yielded proof of the presence of the bacillus. The authors stress the fact that synovial biopsy with the aid of modern technical resources is devoid of danger but should be employed only when the bacillus cannot be demonstrated otherwise, either in situ or in a tuberculous lesion localized elsewhere.

*Behavior of Draining Bronchi During Cavity Aspiration. S. Chiodi and M. Gemmi.—p. 454.

Bronchi During Cavity Aspiration.—Chiodi and Gemmi of the Forlanini Institute studied the condition of the draining bronchi in the course of cavity aspiration in 50 cases. They injected iodized oil into the cavity by way of the intrathoracic catheter. The quantity of oil necessary to fill the cavity and the bronchi diminished as the treatment progressed. In the early stages of the treatment a cavity may be without a patent bronchus, or it may possess closed bronchi which may open on postural change or by the impulse of a cough, or it may possess large draining bronchi. The cavity may be either single or in communication with another cavity. The intracavitary, pericavitary and extracavitary bronchi frequently present dilatation. The size of the cavity becomes greatly reduced in the course of the treatment. At this stage the cavity may be without a draining bronchus or the bronchi may be undergoing progressive narrowing and closure, which can be verified roentgenologically, or, on the other hand, the bronchus or the bronchi may remain patent throughout the treatment. When the cavity is entirely obliterated the bronchi draining it are apparently closed. The clinical condition of the patient corresponds to the phase of the disease as shown in the roentgenograms. Patency of the bronchi after the supposed obliteration of the cavity is an indication for continued suction. The existence of bronchiectasis or of a fistula of the tract occupied by the catheter can be ascertained by roentgen examination with the aid of iodized oil.

Posttraumatic Pressure on the Brain.—Irsigler characterizes the changes which the posttraumatic brain pressure produces in the brain itself and on the liquor spaces as follows: 1. Posttraumatic brain pressure develops in the majority of cases on the basis of a reactive brain swelling which develops from a collateral edema around the traumatic lesion and which may gradually extend over the entire hemisphere. 2. This cerebral swelling as a rule produces clinical signs of a generalized increase in brain pressure three or four days after the trauma. Pressure symptoms which appear within the first two days or even within the first twenty-four hours after the injury are nearly always caused by an intracranial hematoma. Although practically the same form changes and mass deviations are produced by the cerebral swelling and by the pressure resulting from intracranial hemorrhage, the difference in time between the appearance of the symptoms of these two types of pressure is one of the most important factors in the differentiation of these two traumatic sequels. 3. Brain injuries may be followed by incarceration in the tentorial notch with pressure on the brain stem and the quadrigeminal plate. The result is a compression of the aqueduct of Sylvius with hydrocephalus of the ventricle. The incarceration explains also certain symptoms of the midbrain such as anisocoria or disturbances of the conjugated eye movements, which occur in persons with brain injuries. Unilateral pupillary dilatation and unresponsiveness to light is not always indicative of an intracranial hemorrhage; it is merely a sign of pressure on the tentorium of the midbrain, and thus it may accompany cerebral swelling as well as hemorrhage.

Treatment of Vertebral Fractures.—Böhler demonstrated in 1930 that by the reduction of vertebral fractures the lumen of the vertebral canal and of the vertebral foramina can be restored, and that in this manner the paralysis is avoided in all cases in which the continuity of the cord has not been severed. Many observers have reported good results from this method. It is superior to laminectomy, because it is less complicated and involves no danger of infection. Böhler made careful studies on more than 60 cadavers in which vertebral fractures had caused paralysis. He observed the effects of longitudinal extension, ventral suspension and dorsal suspension. Böhler classifies the vertebral fractures into: 1. Cases without deviation, in which the paralysis is due to concussion, hemorrhage or edema. In these cases the paralysis disappears spontaneously. 2. Cases with pronounced anterior dislocation of the cranial fragment in which the vertebral arch is preserved. In these cases the spinal cord is crushed, and reduction, like any other treatment, is without avail. 3. Cases with unilateral or bilateral fracture of the arch in the interarticular portion. In these cases there exists usually only compression, not severance of the cord, and they are suitable for nonsurgical reduction. 4. Cases with comparatively slight dislocation and hooking of the articular processes in which the spinal cord is usually preserved. These can be reduced in ventral or dorsal suspension after previous partial resection of the articular processes. With regard to vertebral fractures without paralysis, Böhler states that before 1929 he applied a plaster bed in hyperextension and gradually reduced the gibbus as in spondylitis. A report by Davis, an American author, convinced him that immediate reduction is preferable. Böhler employed reduction and subsequent fixation in a plaster cast, but instead of keeping patients in bed with a cast he lets them up and makes them do gymnastic exercises to avoid muscle atrophy. The treatment embodies the same three principles of reduction, fixation and exercise which govern the treatment of bone

fractures in general. To Magnus's objection that the vertebral body may later collapse and that the length of time the cast has to remain in place is a disadvantage, Böhler replies that for fractures without paralysis the immobilization requires on the average less than four months, and for fractures with paralysis on the average six months. Breaking down of the vertebra does not occur if the reduction was complete and was done within the first few days after the accident. It may occur if the reduction was done late or if the fixation was of insufficient duration. To Magnus's charge that the method is expensive, time consuming and annoying to the patient, Böhler replies that reduction is done on the first day and that the patients are up and exercising on the second day. Patients in whom the fracture is not complicated by paralysis and whose occupation does not involve hard physical labor can leave the hospital after seven days and resume their work during the second week. After six weeks, when patients treated by the method of Magnus begin to walk with the aid of supports, Böhler's patients already carry weights of from 20 to 40 Kg. on their heads. Unreduced vertebral fractures are generally extremely painful for a number of days, whereas, when the fracture is reduced, the patient is free from pain provided the reduction is complete and the plaster jacket fits well. The exercises create self confidence and pride in performance. This can be attested by thousands of physicians who have visited Böhler's clinic and have observed the patients.

Functional Treatment of Vertebral Fractures.—Burkle-de la Camp discusses the relative merits of the Böhler treatment of vertebral fractures by reduction, fixation in plaster and exercises, and the functional treatment defended chiefly by Magnus. In the functional treatment the patient is kept recumbent on a thin mattress under which a board is placed. Sand bags are used to effect a gradual reduction of the hump if the gibbus is considerable. During the first two weeks the patient lies on his back but is permitted to lie on a side for short periods. Heat is applied by means of a heating pad. From the third week on heat is applied with the patient in the prone position and the musculature of the back, excluding the region of the fracture, is massaged. With the beginning of the fifth week the patient is raised to sit up in bed at meal time; this is gradually increased to a regular exercise. After six weeks the patient gets up and is usually able to bend over without holding the vertebral column stiff. Gymnastic exercises are begun. The patient is able to work after an average of one hundred and thirteen days. In the less severe injuries the time required for treatment is shorter (from six to seven weeks). The author analyzes the results obtained in a hospital in a mining region, in which during one year 230 fresh vertebral fractures were treated and in which annually from 500 to 600 old vertebral fractures were reexamined. He employed the technic which Böhler has outlined in the latest edition of his book on fractures. He concludes that it is possible to reconstruct a broken vertebra, that such a vertebra will bear loads and that the function of the vertebral column will be completely restored. Some of these vertebrae, however, will break down in spite of the reduction and sufficiently prolonged fixation. After the reduction treatment there is a greater loss of elasticity than is the case with the functional treatment. The reduction treatment does not produce a more rapid improvement in the paralysis; it may even produce or intensify paralysis, because a bone fragment or a portion of the intervertebral disk may enter the vertebral canal and exert pressure on the cord. The prolonged wearing of a plaster jacket often weakens the patient besides producing unfavorable psychologic effects. The reduction treatment did not prove advantageous in the author's material. He considers prevention of gibbus formation an insufficient justification for Böhler's treatment and considers the functional treatment best.

Conservative and Surgical Treatment of Ureterolithiasis.—According to Boeminghaus the majority of ureteral calculi are discharged spontaneously or with conservative or instrumental aid. The evaluation of the consecutive methods is difficult, because it is almost impossible to determine whether the stone could not have been discharged spontaneously. Instrumental removal of ureteral calculi usually consists in the employment of the loop catheter. It is highly gratifying

to be able to relieve a patient, tortured by colic and fever and threatened with severe renal impairment, by a simple cystoscopic procedure. Even in cases in which spontaneous expulsion appears likely the instrumental removal of the stone will save the patient days or weeks of suffering and considerable renal damage. There is no other condition in which the art of instrumental treatment is associated so intimately with major surgery as in the treatment of ureteral stones. The greater the mastery over the conservative methods, the smaller is the number of surgical interventions. In case of complete obstruction, the removal should not be postponed for more than two or three weeks. It is erroneous to estimate damage produced by stasis on the basis of the dilatation of the renal pelvis alone. If blockage is associated with urinary infection, the situation is urgent. If the urine can flow alongside the stone, an expectant attitude is permissible but reexaminations become necessary. Increase in dilatation, lowered renal function and a complicating infection make prompt removal of the stone imperative. The higher the ureteral obstruction, the greater and more rapid the destruction of the kidney. The misgivings about surgical intervention for ureteral stone are often unduly exaggerated. The necessity for such an intervention is determined by the duration of symptoms, the degree of urinary stasis, the type and intensity of urinary infection and the extent of the functional impairment of the kidney. Consideration of the opposite kidney is important. The presence of a ureteral stone is especially dangerous if the other kidney has already suffered. The decision as to when renal damage becomes irreparable, so that nephrectomy is necessary, should not be schematic. The author is of the opinion that there is too great a tendency to perform radical operations when kidney-preserving interventions, such as a temporary renal fistula, would accomplish the aim. Roentgenoscopy should be made immediately preceding the intervention, because the stone may have altered its position. The incision should not be too small. The ureter should always be opened in the longitudinal direction, because an extensive longitudinal incision is less harmful than a short transverse one. The patency of the ureter must be explored after extraction of the stone. In cases in which a ureteral stone exists on one side and a renal stone on the other, the ureteral stone should be removed first, because it is more harmful to the organism. In the case of bilateral ureteral calculi or of a patient with one kidney and a ureteral stone, there is present the danger of anuria. Surgical removal in such cases must be resorted to within twenty-four to thirty-six hours after the development of anuria.

Hormone of Thymus.—Bomskov claims to have discovered the hormone of the thymus. Investigations by Bomskov and several collaborators began with studies on the utilization of the hypophyses of whales in the pharmaceutical industry. The whale hypophyses were examined for their hormone content, and comparative tests were made on the hypophyses of cattle. There are five known hormones of the anterior hypophysis: the thyrotropic, gonadotropic, lactotropic, growth and diabetogenic hormone. The first three are comparatively well known. The investigators gave their attention chiefly to the last two. Evidence was produced which made it probable that the growth hormone and the diabetogenic hormone are identical. Further studies aimed to determine whether the growth (diabetogenic) hormone exerts its action directly or whether it is a "tropic" hormone, that is, one which acts by way of some incretory gland. Studies were undertaken to determine whether this hormone is active in thymectomized animals. Roentgen rays were used to effect a practically complete destruction of the thymus tissue. In animals subjected to such roentgen irradiation of the thymus the diabetogenic (growth) hypophysial hormone proved to have no effect on the hepatic glycogen, suggesting that the action of the hormone is dependent on an intact thymus, or, expressed differently, the hormone is the thymotropic hormone of the hypophysis. The identification of the thymotropic hormone led to a search for the thymus hormone. Experiments with a lipid extract of the thymus demonstrated that the thymus hormone is a lipid substance. The thymus hormone produces intense growth in animals. It is effective in hypophysectomized rats and produces diabetes. A single injection of the hormone produces

pronounced lymphocytosis and leukocytosis. Continued injection, over a period of several weeks, causes involution of the male gonads and their adnexa. All these effects of the thymus hormone, which can be produced also with the thymotropic hormone of the anterior pituitary, but only in the presence of an intact thymus, are manifestations of infantilism (intense growth, lymphocytosis, smallness of gonads and low glycogen content). Investigations on the formation and action of the thymus hormone disclosed that lymphocytes, after they have been formed in the lymphatic tissues, are attracted toward the thymus. Passing through the medulla of the thymus, they are charged with the thymus hormone. These charged lymphocytes are stored in the cortex of the thymus, are discharged into the lymph stream as needed and are carried to the sites where their action is required. The author compares this mode of action with conservation in cans. The cans (lymphocytes) are produced in the lymphatic tissues; filling of the cans takes place in the thymus, which represents the canning factory, from which they are carried to places where their contents are consumed. The thymus hormone differs from other hormones in that it is not dissolved in the plasma but is carried by the lymphocytes. The author developed a method which makes possible the detection of thymus involvement in various disorders. It enables him to detect in 50 cc. of urine the thymotropic hypophysial hormone as well as the thymus hormone.

Clinical Consideration of Thymus Hormone.—According to Rehn, hyperfunction of the thymus leads to disease if it disturbs the hormonal equilibrium required by the age and vital functions of the subject. He directs attention to certain changes in the liver and heart, particularly to glycogen deficiencies in these organs; also to the relation between thymus, thyroid and gonads at birth and at puberty. He suggests that hyperfunction of the thymus at puberty probably plays a part in acromegaly and eunuchoidism. Status thymicolymphaticus, that is, infantilism, can be induced by means of the thymus hormone. The author pays particular attention to the role of the thymus in exophthalmic goiter and points out that in patients with this condition the function of the thymus should be tested as well as the basal metabolism. Glycogen deficiency in the liver of patients with carcinoma led to studies on the thymus function of such patients and disclosed hyperfunction. Since the lymphatic system plays an important role in transporting the thymus hormone, it seemed desirable to test the thymus function in a disease seriously involving this system, namely in Hodgkin's disease. Tests on patients with Hodgkin's disease revealed such a severe hyperfunction of the thymus that a hormonal disturbance must be accepted, although its primary or secondary character cannot be determined as yet.

Rapid Treatment of Syphilis.—Hoffmann discusses the massive dose chemotherapy of early syphilis by the intravenous drip method. He points out that Americans compare this method only with the continuous alternating treatment, which requires at least two years, but not with the method of Hoffmann, which consists of maximal early treatment with simultaneous exhibition of neoarsphenamine or sodium arsphenamine and a bismuth compound in from one to three courses of treatment. With this method the spirochetes usually disappear from the cutaneous and mucous membrane lesions after twenty-four hours and the serologic and clinical signs subside quickly. The arsphenamine drip method represents nothing new, whereas its great inconvenience and the frequency of threatening toxic manifestations make its employment inadvisable. A real "lightning" cure of the type of therapia sterilisans magna is possible in three days

by means of the originally practiced intragluteal application of arsphenamine, particularly in the form of the "double shot." The author cites the history of a man who in 1910 developed a severe secondary syphilis which relapsed after simple inunction treatment. Months later, when he had a severe papulo-ulcerous syphilis with severe syphilitic angina, the patient decided to undergo arsphenamine treatment. Arsphenamine was injected intravenously and an intragluteal injection was given three days later. The rapid disappearance of all signs of syphilis proves that this double shot method, in which the intragluteal "catch shot" is especially important, will cure within three days not only early syphilis but also old cases. The author reviews 5 similar cases. He prefers sodium arsphenamine to other preparations. The 6 reported cases in which "lightning" cures were obtained by the intragluteal administration of arsphenamine were observed for from eighteen to thirty years. The violent therapeutic inflammation in the muscle seems to play an important part in this form of chemotherapy. The intravenous administration of arsphenamine with and without mercury has likewise produced excellent permanent results, particularly if adequate single doses are repeated with sufficient rapidity. The so-called double shot (intravenous plus intragluteal) has produced the best results in the author's experience. The development of the combined early treatment with neoarsphenamine and sodium arsphenamine and a preparation containing basic bismuth salicylate has made it possible to dispense with arsphenamine for early cure. The one to three course system insures permanent cures in nearly 100 per cent of the cases of primary and secondary syphilis, if sufficiently large single and weekly doses are administered and if the intervals between courses are short (four to five weeks). This has been proved by follow-up observations with serologic tests over periods of from two to three decades.

Organic Angina Pectoris Electrica.—Koeppen observed 93 cases of electrical accidents that were followed by cardiac disturbances. He first presents cases in which the electrocardiographic record disclosed a coronary insufficiency combined with disturbances of the cardiac function. In a second group of cases the electrical accident was followed by auricular fibrillation and flutter. All of these latter patients were comparatively young. Further the author presents a group of cases which, like those in group 2, present disturbances in the cardiac conduction. To clarify the development the author investigated the site of attack of the electrical energy on the heart in animal experiments. He also directs attention to investigations by American workers who demonstrated that the cardiac defects, particularly the ventricular fibrillation, can be elicited by electrical irritation only during the so-called relative refractory phase, whereas in the case of irritations during the absolute refractory time the electrocardiogram discloses no disturbances. The author offers as an explanation for this that during the relative refractory phase the resting action currents of the heart are covered up or disturbed by the technical current and that thus the conduction of the stimulus, the subsequent stimulation of the auricles and ventricles cannot be effected. He thinks that his own experiences and those of the American authors permit the conclusion that an electrical injury of the heart can be accepted only if the accident was immediately followed by cardiac disturbances, but that anatomically demonstrable changes cannot be expected because the current acts only an extremely short time. In the summary he states that 16 of his 93 cases presented the aspects of organic angina pectoris electrica. This disorder is due to an impairment of the stimulus conduction system; that is, of the formation of the stimulus as well as of its course. Electrocardiographically, the disorder presents itself (1) as a coronary insufficiency, (2) as an auricular fibrillation and (3) as disturbances in the conduction of the stimulus. The author regards electrical angina pectoris as a result of direct electrical action on the cardiac conduction system.

*Lipoid Extracts in Therapy of Heart Disease. E. Albrich.—p. 935.
Requirements for Successful Irradiation of Malignant Tumors. J. von Palugay.—p. 939.

Lipoid Extracts in Therapy of Heart Disease.—Albrich points out that Latzel and later Thaler used lipid extracts successfully in the treatment of lesions of coronary vessels. The lipid extracts are prepared from several organs. The author employed the cardiac type in combination with the aortic and occasionally the cerebral type. According to Latzel's suggestion, the preparations are administered intracutaneously (corresponding to Head's zones), usually parasternally, in the second and third intercostal space. Albrich maintains that these lipid extracts can be successfully employed (1) in calcifications of the coronary vessels and its sequels, especially in myocardial infarct and in chronic myocarditis; (2) in acute myocarditis that can be traced to a focal infection; (3) in essential hypertension with decompensated heart and encephalomalacic foci; (4) in decompensated organic heart defects (as supporting therapy), and (5) in cases of cardiac myodegeneration. The author reviews the histories of 5 patients with calcification of the coronary vessels. Cases of this type can be treated successfully by diet and lipid extracts. That the efficacy of this treatment is not due to suggestion was proved by test injections of physiologic solution of sodium chloride. In 2 cases of tonsillogenic myocarditis the customary treatment was not dispensed with and, after the cardiac status had improved, the focus was removed; but here too lipid therapy proved to be a valuable adjuvant. It was found that blood pressure could not be modified in patients with essential hypertension and cardiac failure by the lipid extract alone. Hospitalized patients were given a restricted diet, digitalis and pressure reducing substances, but even in these patients the author does not want to dispense with two or three weekly injections of the lipid extract. Injections of lipid extract are continued for several weeks after compensation has been restored. Decompensated organic heart defects must be treated with strophanthin and digitalis. In these cases, as well as in those of myodegeneration, the authors regard the lipid extract as an adjuvant.

- *Stool Examinations in Elementary School Children, with a Note on Santonin Treatment. M. Ro.—p. 1975.
*Clinical Studies of Bronchial Asthma. K. Yogi.—p. 1989.

Santonin for Ascaris.—Ro examined the stools of 465 elementary school children in an agricultural area in northern Formosa and discovered the highest rate of any one infestation to be that of *Ascaris lumbricoides* (85.35 per cent in males, 89.10 per cent in females), followed by *Trichocephalus trichiuris* (78.75 per cent in males, 68.58 per cent in females) and hookworm (23.73 per cent in males, 15.38 per cent in females). Among the pathogenic protozoan infections in the lower range of frequency were *Giardia lamblia* (15.15 per cent in males, 12.82 per cent in females) and *Endamoeba histolytica* (3.03 per cent in males, 1.92 per cent in females). The results of these examinations revealed 70.05 per cent of children infected with helminths without protozoa, while only 0.84 per cent were infected with protozoa without helminths. Mixed infection with both helminths and protozoa was encountered in 25.14 per cent of children; the combination most frequently seen was *Ascaris*, *Trichocephalus* and *Giardia*. A single administration of santonin, in doses varying from 0.03 to 0.05 Gm. according to the age of the child, followed two hours later with a 10 per cent infusion of senna leaves mixed with 40 per cent of magnesium sulfate (24 to 30 cc. diluted with water to 150 to 200 cc.) produced a complete cure in 50 children (22.43 per cent) and the satisfactory expulsion of 1,439 ascarids in 362 children (77.84 per cent). The ratio of male worms expelled was 39.16 per cent.

Bronchial Asthma in Formosa.—Yogi analyzed 420 cases of bronchial asthma seen during a six year period in Taihoku, a city in northern Formosa having a subtropical climate. As

compared with the published reports of incidence of asthma in Japan proper, the author found here a higher morbidity rate, especially during the season characterized by high humidity (from October to May). The condition is more frequently seen in Japanese who migrated to Formosa and became afflicted with the disease during the first four years or during the period of acclimatization. Men are most susceptible to the disease in the age period between 26 and 30 years, and women between 16 and 20 years. No difference was noted in the possible hereditary and sex factors as compared with reports from other countries. In the majority of patients with bronchial asthma, allergic cutaneous reactions were positive, the rate of positive reaction being higher in asthmatic than in normal subjects. As a rule normal subjects react positively to a single allergen, while the asthmatic patients usually show positive reactions to several allergens. As compared with the nature of cutaneous reactions in asthmatic patients in Japan proper, patients in Formosa appear to be more highly sensitive in cutaneous reactivity. The incidence of positive cutaneous tests for fungus and yeast were especially high among the asthmatic and even among normal subjects, suggesting the potency of the microbiologic flora of Formosa, to which the inhabitants are constantly exposed. The Prausnitz-Küstner tests and the provocative tests often produced results at variance with each other; these tests are to be used merely as an adjunct in clinical diagnosis of asthma and not as a means of explaining the nature of the disease.

*Subcutaneous Injections of Oxygen in Therapy of Lesions of Respiratory Organs Caused by Irritating Gases. I. Ya. Sosnovik. —p. 22.

Subcutaneous Oxygen for Toxic Bronchitis from Gases.—Sosnovik reports 61 cases of toxic bronchitis, bronchiolitis and bronchopneumonia caused by irritant gases in various industries and treated by subcutaneous injection of oxygen. Nitric acid fumes, phosgene, chlorine and chlorpicrin were the offending substances. Oxygen was introduced subcutaneously in amounts varying from the initial dose of 200 cc. to 1,000 cc. every other day; in cases of pneumonia and bronchopneumonia 1,000 cc. was injected daily. The immediate effect was that of improvement in the subjective feeling, followed by diminution of cough, the sensation of tightness in the chest, dyspnea and the amount of sputum, with improvement in appetite and sleep. Oxygen therapy appeared to exert an analgetic and sedative effect. The author regards it of value as a supplementary measure in the treatment of acute and subacute bronchitis caused by irritating gases. The therapy was without any effect in chronic toxic bronchitis.

Differential Diagnosis Between Pulmonary Tuberculosis and Pneumonia: Illustrated by Larger Material. S. Holm and K. Winge. —p. 2121.

*Occurrence of Aseptic Complications in Central Nervous System in Scarlet Fever. H. C. A. Lassen and J. Bang. —p. 2130.

Aseptic Complications in Central Nervous System in Scarlet Fever.—Lassen and Bang report that, of 9,826 cases of scarlet fever treated at the Blegdam Hospital from 1934 to 1940, 20 (0.2 per cent) presented symptoms of complications in the central nervous system. There was increased number of cells, predominatingly lymphocytes, in the spinal fluid in all cases; in 6 cases the pleocytosis was the only sign of the disorder of the central nervous system. In 10 there were clinical signs of meningitis without focal symptoms; in 4 there were focal symptoms. The prognosis was good in all cases. The complications are ascribed to a virus infection which is, however, not believed to be of "poliomyelitic" kind, although 16 of the cases occurred during the months from August to Novem-

ber. The authors found no demonstrable correlation between the occurrence of these aseptic infectious disorders of the central nervous system and scarlet fever with neurologic symptoms.

Hygiea

*Mesenterial Pyemia in Connection with Appendicitis. H. Rosenqvist. —p. 2159.

Mesenterial Pyemia with Appendicitis.—Rosenqvist says that the picture of mesenterial pyemia is characterized by chills and signs of disturbance of the liver. Mesenterial pyemia may occur, usually in men between 20 and 50, in spite of early operation for appendicitis. Chills in appendicitis are an absolute indication for immediate operation. If on operation thrombosis is found in the mesenteric lumen, the mesenteric lumen must be resected as extensively as possible. If thrombi extend to a greater degree in the proximal direction, ligation of the ileocolic vein should be tried. In threatening pyemia immediate antiseptic treatment with sulfonamide derivatives and heparinization are important. Three personal cases are reported.

Hospitalstidende

*Annular Pancreas. F. Truelsen. —p. 2226.

Annular Pancreas.—Truelsen says that he observed this anomaly, the first to be published in Scandinavian literature, in a man aged 35 with a history of periodic mild gastric attacks for years; aggravation of the attacks and lessening ability to work led to hospitalization. The roentgen diagnosis was duodenal diverticulum. Operation disclosed an annular pancreas with marked dilatation of the duodenum above it. Duodenorrhaphy was done, with gastroenterostomy. Half a year after the operation the patient was without symptoms and fully able to work. The author finds 43 cases of annular pancreas, in both sexes and all ages, recorded in the literature, with more or less marked symptoms of high intestinal obstruction described in 16; operation was performed in 7 cases; the remaining were diagnosed at necropsy. In most cases, he says, an annular pancreas may give few or no symptoms for years or through life. When surgical treatment is indicated, an anastomosis should be the method, probably a gastroentero-anastomosis, in cases of marked dilatation perhaps a duodeno-jejunosomy, or, as in his case, a gastroenterostomy with duodenorrhaphy, to hinder continued retention in the duodenal sac.

Norsk Magasin for Lægevidenskapen

*Peduncular Brain Stem Syndrome. K. Kristiansen. —p. 2241.

Peduncular Brain Stem Syndrome.—A man aged 53, had had hemianopic disturbances in vision of migraine-like character setting in many years earlier, then symptoms, at first transitory, of a disturbance which, viewed in retrospect, is assumed to have been the first manifestation of the lesion in the right dorsorostral part of the brain stem which was established later. Kristiansen says that dissociated loss of sensibility, hyperpathia and spontaneous pain indicate that the thalamus must also have been affected somewhat early in the course. The last ten or twelve years of the patient's life were most marked by epileptiform manifestations, diplopia as the result of paralysis of the oculomotor nerve, first on the right side, later also partly on the left side, grotesque involuntary movements in the left upper extremity preeminently appearing as hemiballism and, finally, disturbing sensory phenomena on the left side. About the time of the onset of the peduncular symptoms the patient, formerly silent and taciturn, became talkative and cheerful. Death was due to bulbar symptoms. There was a crossed brain stem syndrome, distinguished from the ordinary vascular hemisindrome by the extension of the lesion to the other side of the middle line. The author finds that the post-mortem establishment of an expansive process in the form of a cavernous hemangioma justifies not accepting a purely vascular genesis in such cases but considering the probability of a neoplasm. The hemiballism was due to a lesion of the sub-thalamus. With regard to the psychic changes which may appear in patients with disorders in the rostral part of the brain stem the tendency to affective instability is stressed. To what extent the migraine-like symptoms in the case were connected with the lesion of the brain stem is uncertain.

Book Notices

Military Medical Manual. Foreword by Major General James C. Magee, the Surgeon General, U. S. Army. Fourth edition. Cloth. Price, \$4.50. Pp. 877, with illustrations. Harrisburg, Pa.: Military Service Publishing Company, 1940.

This edition brings up to date information on subjects of interest to officers of the Medical Department of the Army. The sources of the subject matter are the official publications of the War Department and instructional material published by the general and special service schools. Part one deals with purely military subjects, such as the composition of the Army, mobilization planning, supply and evacuation of military units, defense against chemical warfare, map reading, interpretation of aerial photographs and the care and operation of motor vehicles. Part two deals with medical subjects. Of particular interest is the chapter devoted to the history of the evolution of the Medical Department of the United States Army. By the act of Congress in 1818 there was created a Medical Department of the Army, a Surgeon General was appointed and a central organization was set up. This marks the transition from the individual, haphazard and largely inadequate medical service to one of central organization and definite progress. It is indeed a record to be proud of. The Army was one of the first organizations to put many of the modern health measures into practice with demonstrable success. Among these may be mentioned routine immunization against typhoid, smallpox and diphtheria, and the control of venereal disease. The Army Medical Department established opportunities for and encouraged research. It had added, in the course of years, many an illustrious name to the roster of pioneers in the fields of bacteriology and sanitation. Thus, Major C. R. Darnall originated and devised a method of purifying water by means of chlorine. Major Walter Reed demonstrated the transmission of yellow fever by the mosquito, and Col. William Gorgas had eradicated the yellow fever and had thus enabled our Engineer Corps to accomplish the engineering feat at which the French had failed—the building of the Panama Canal. Compulsory vaccination against typhoid was introduced in 1911. Bacteriology was not the only science advanced by the Army Medical Department. The first American experimental physiologist was a surgeon in the United States Army, William Beaumont. The success in research work is due to the well trained personnel, who are encouraged to carry on their investigations, and to the fact that the Army has large groups of men under control which facilitates investigation and permits follow-up of the results. Thus the Army Medical Department has been able to make many advances in medicine that have been of service to humanity. A Medical Research Coordinating Board was appointed Jan. 15, 1940 to facilitate research problems in the Army. An invaluable gift to medicine is the creation of the Army Medical Library, the largest and greatest medical library in the world. The remaining chapters in part two deal in considerable detail with such subjects as field sanitation, military preventive medicine, military hygiene, first aid, aviation medicine and chemical warfare. Part three contains detailed information regarding the tactical employment of medical units in the field, administration, supply and mess management. The existence of an emergency, with the consequent increase of the medical personnel of the Army, makes the appearance of the fourth edition of this excellent manual timely and welcome.

The 1940 Year Book of Physical Therapy. Edited by Richard Kovács, M.D., Professor and Director of Physical Therapy, New York Polyclinic Medical School and Hospital, New York. Cloth. Price, \$2.50. Pp. 464, with 149 illustrations. Chicago: Year Book Publishers, Inc., 1940.

This is the third edition of the Year Book of Physical Therapy. Although it is the newest of the series of year books, this yearly volume on physical therapy has amply proved its value. As in previous years, the book has been edited by Dr. Richard Kovács, whose wide experience and knowledge of many languages admirably suit him for the work of compiling the available yearly information on the subject of physical therapy. The fortieth anniversary of the Year Book series is now being

celebrated, and the editor in recognition of this fact has inserted an introductory article on the treatment and management of arthritis. Throughout the text, from this introductory article to the final section on applied physical therapy, there will be found much valuable material of interest not only to the specialists in physical therapy but also to the general practitioner and to specialists in many other fields. It is stated that the aim of the book is "to present side by side all organized methods of physical treatment and to stress on all occasions that they are only parts of the extensive field of general medicine." An inspection of the contents of the book reveals that this aim has been accomplished. Methods of treatment are considered under such headings as thermotherapy (fever therapy and cryotherapy), electrotherapy, light therapy, hydrotherapy, balneotherapy and climatotherapy, massage, exercises, posture and related topics. Of general interest are the sections dealing with application of physical agents for the treatment of cardiovascular conditions and diseases of the respiratory and gastrointestinal tracts, as well as the sections on arthritis and traumatic lesions. Of particular interest to specialists in other fields are the sections on orthopedic conditions and sections on neurology, pediatrics, gynecology, urology, proctology, dermatology and ophthalmology. The text is replete with information which would be valuable to the younger physician who is searching for a problem in clinical or experimental research. It presents a well rounded and broad picture of the recent developments in physical therapy. It is a work which any practitioner could read with considerable advantage.

Cunningham's Manual of Practical Anatomy. Revised and edited by J. C. Brash, Professor of Anatomy in the University of Edinburgh, Edinburgh, and E. B. Jamieson, Lecturer on Anatomy in the University of Edinburgh. Volume I: General Introduction, Upper Limb, Lower Limb. Volume II: Thorax and Abdomen. Volume III: Head and Neck; Brain. Tenth edition. Fabrikoid. Price, \$4.25 per volume. Pp. 411, with 194 illustrations; 500, with 238 illustrations; 535, with 236 illustrations. New York, Toronto & London: Oxford University Press, 1940.

It seems fitting that the fiftieth year of the life of this book should be marked by a new edition. Several earlier editions required two impressions, one required three. It is not only a guide to dissection but also a textbook of regional anatomy. In crowded dissecting rooms, where all workers must follow one plan so as not to get in one another's way, it is excellent: in conditions of less crowding and hurry it has one defect—it teaches the student to "verify" some one else's observation instead of making his own. That is not the best training for a future practitioner. The ninth and tenth editions have been prepared by Professors Brash and Jamieson of the University of Edinburgh. In them the directions for dissection are slightly altered. The text is improved and slightly abbreviated. Relatively more attention is given to surface anatomy, lymph drainage, radiography and clinical application. The nomenclature recommended by English anatomists is used, but the BNA names are given in a comparative list in the introduction. Measurements are English: inches replace centimeters, and weights are not stated. It has been the most widely used and the most popular dissecting manual in the language. Most English speaking physicians are well acquainted with it.

Die biogenen Amine und ihre Bedeutung für die Physiologie und Pathologie des pflanzlichen und tierischen Stoffwechsels. Von M. Guggenheim, Dr. phil. et med. h. c. Third edition. Cloth. Price, \$11.25; 48 Swiss francs. Pp. 564. New York: Nordeman Publishing Co., Inc.; Basel: S. Karger, 1940.

The second edition of this book appeared in 1924; the present edition has been completely rewritten to incorporate the major developments represented by the large amount of data accumulated in the intervening sixteen years. George Barger (The Simpler Natural Bases, New York, Longmans, Green & Co., 1914) first recognized the desirability of assembling in systematic form the data on various chemical groups which are related in biologic importance and methodology. Guggenheim (who dedicates his work to Barger) has devoted his efforts to bring together such data for the naturally occurring amines and related synthetic substances. The point of view throughout is that of the organic chemist who appreciates the pharmacologic and biologic importance of his chemicals. A short section on the general properties and methods of study of these amines is fol-

lowed by concise but rather exhaustive discussions of the amines arranged in sections according to their chemical classification: alkyl amines, betaines, diaminocarboxy amines and the like. The ordinary amino acids are not treated as a group but are taken up in the sections where they naturally belong in systematic organic chemistry. The largest proportional space is given to the substances of greatest medical importance, such as choline, creatine, histamine, epinephrine and related compounds. In general, the order of discussion is discovery, occurrence, synthesis, isolation and analysis, biochemical and pharmacologic properties and relations. There are four thousand, one hundred and fourteen cited references, so it is hardly surprising that details of biologic experiments and evidence are not given. There are no illustrations, but atomic and structural formulas are abundant. The book is an indispensable reference work for the organic chemist working with the simpler amines of biologic importance. The absence of an author's index and the brevity of the subject index are regrettable. The investigator whose organic chemistry is wanting may have difficulty in quickly finding the information he desires.

The Art of Surgery: A Text-Book for Students and Practitioners. By H. S. Souttar, D.M., M.Ch., F.R.C.S., Surgeon, London Hospital. In Two Volumes. Fourth edition. Fabrikoid. Price, 25s. per set. Pp. 402; 403-779, with illustrations. London: William Helmhmann, Ltd., 1940.

The British have developed a number of small surgical compends, some of which are deservedly popular. The present work represents such an effort. It is directly aimed at the teaching of surgery to the British student and probably has less value for the American. The art of surgery can surely be advanced by correlation of such reading with experience. The matter is contained in two small handy volumes, which must be convenient to war harassed students. The index, however, should appear in both volumes instead of only in the second. The books contain brief, but lucid and accurate, pictures of usually common surgical conditions and present clear clinical descriptions of many surgical problems. They are aptly illustrated by small sketches. There is no question that in this effort the author has managed to fulfil his intentions. He has a warm style of writing, which is different from the crisp discussion found in the usual American textbooks. Some of the scientific accuracy which we have come to expect is lacking. Hardly any mention is made of the newer knowledge which has brought such great strides in surgical progress. The various vitamins, chemotherapy, continuous intestinal nasal suction, fluid balance and electrolyte replacement receive almost no attention. Surely these are of vital import to the artful surgeon! Unfortunately, the various revisions have not been too thorough. On page 534 the author states that gastroenterostomy was introduced in Billroth's clinic forty-five years ago. This dates the books as ten or fifteen years behind the times, a concept fully supported by the failure to include the recent highly profitable advances in surgery.

Medical Genetics and Eugenics. By Charles B. Davenport, B.S., A.B., A.M., Clyde E. Keeler, B.S., M.A., M.S., Maude Slye, A.B., Sc.D., Director of the Cancer Laboratory, Otho S. A. Sprague Memorial Foundation, University of Chicago, Chicago, and Madge Thurlow Macklin, A.B., M.D., LL.D., Associate Professor of Anatomy, Western Ontario Medical School, London, Ontario, Canada. Cloth. Price, \$1. Pp. 141, with 51 illustrations. Philadelphia: Woman's Medical College of Pennsylvania, 1940.

If the reader interprets the title of this book literally he is sure to be disappointed, for this is not a compendium or a comprehensive treatise. It is merely a rather elementary series of six lectures on certain aspects of general human genetics, with emphasis on the medical and eugenic phases of the subject. The lectures, three by the veteran human geneticist C. B. Davenport and one each by the other authors, were delivered at the Woman's Medical College of Pennsylvania in March 1940 in connection with the nineteenth anniversary of the founding of the college. Dr. Davenport presents in interesting form the well known standard data on human variability and mate selection, on some social applications of eugenics, and on heredity in relation to medicine. Dr. Keeler, in a short but interesting chapter, discusses the value of animal experiments to the understanding of human genetics. Dr. Slye reviews her own work

in a chapter on cancer and heredity and draws certain conclusions from her work with mice as to the control of cancer in human beings. Dr. Madge Macklin, in her chapter on the value of medical genetics to the clinician, urges that medical genetics be taught in medical schools. Case studies are presented in which the value of knowledge about hereditary diseases is demonstrated as part of the equipment of the well rounded clinician.

Shoes and Feet: A Text Book for Students and Practitioners. A Practical Consideration of Fifty Affections of the Foot Found in Chiropractical Practice: Their Relationship to Shoes, and Their Elemental Treatment. By Frank J. Carleton, D.S.C., Professor of Mechanical Orthopedics and Lecturer in Shoe Therapy, Temple University School of Chiroprody, Philadelphia. Foreword by R. Ray Willoughby, B.S., M.D., Dean, School of Chiroprody, Temple University. Cloth. Price, \$5. Pp. 357, with 156 illustrations. West Chester, Pa.: Shoes and Feet, the Publishers, 1940.

The author presents, for students and practitioners of chiroprody, a discussion of fifty conditions of the foot which are found in the routine practice of chiroprody. He discusses the relationship of these to shoes and outlines their treatment. The author is evidently well qualified to discuss the subjects contained in the book. He graduated from Temple University in 1922, has had about eighteen years of clinical and private practice and has been performing clinical service on the staff of his alma mater. He has made special studies and has written considerably on the subject. The causes and treatment of local irritations are outlined, the foot being viewed in its reaction to pressure. Conditions pertinent to the chiroprodist's practice are reviewed for the practical application of mechanical alleviation. The book is intended primarily for students. The outline of the history of footwear is well worthy of reading, and illustrations on the evolution of footwear are interesting. He discusses the construction of the modern shoe and goes into detail with regard to shoe manufacture, the basic types of shoes and the measurements and fit of foot gear. There is also a section on pads and strapping for the common disorders of the foot.

Doctors and Doctors, Wise and Otherwise: On the Firing Line Fifty Years. By Dr. Charles McDaniel Rosser. With introductory foreword by Dr. Holman Taylor. Cloth. Price, \$3.50. Pp. 388, with illustrations. Dallas: Mathis, Van Nort & Company, 1941.

Those who know Dr. Charles M. Rosser will be glad to have in book form a reflection of his forceful character, his eloquence and his humor. His contribution to the development of medicine in the Southwest is widely recognized. He gives us pictures of the country doctors of the old school and takes us then to the University of Louisville Medical Department, where he acquired his own education. He tells of his career, which included almost every phase of medical practice, as well as the life of the physician as a teacher and a citizen. What his account may lack in literary skill, it gains in forthrightness. In his career he met most of the great and near great in medical practice. He served his time in the courts and in political relationships; he aided in the extension of medical education to the public and he advanced scientific medical legislation. His concluding chapters explain the attitudes of organized medicine in relationship to the maintenance of standards and of ethics. The book is one which might well be placed in the hands of every young medical student as an inspiration.

Wolf Child and Human Child: Being a Narrative Interpretation of the Life History of Kamala, the Wolf Girl, Based on the Diary Account of a Child Who Was Reared by a Wolf and Who Then Lived for Nine Years in the Orphanage of Midnapore, in the Province of Bengal, India. By Arnold Gesell, M.D. Cloth. Price, \$2. Pp. 107, with 10 illustrations. New York & London: Harper & Brothers, 1941.

Many years ago a missionary in India found a child, aged approximately 8 years, living in a wolf's den. He brought her to an orphanage, where she remained until her death nine years later. At first she reacted to her environment as would any wild animal, but apparently suitable care resulted in adapting her to human ways, although she never quite fully reached her normal human age. The book, which is illustrated with photographs, quotations and comments by Dr. Gesell, is a striking document, a fascinating contribution to ethnology.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT OF SCABIES

To the Editor:—An increasing number of cases of scabies has been experienced for some time in the institution with which I am associated. The physical plant is divided into twelve cottages accommodating about 100 patients each. Cases of scabies have been found in five or six cottages, three of which are thoroughly infested. Persons from other cottages have been working in these cottages having the infestation. Potassium sulfide ointment has been used, and some patients have been cured only to become reinfested soon. Who has had experience in treating a large group in an institution? Please discuss length of treatment (twenty-four hours or three days), agent used and means of treatment. Is it necessary to clean wooden floors on which the patients have been playing and, if so, what method has been found most satisfactory?

Bruce L. Titus, M.D., Salem, Ore.

ANSWER:—The principles of treatment of scabies are the same whether few or many persons are infected, but the difficulties mount with numbers. Only two things are necessary to cure a group of patients with scabies: cure of the individual patient and prevention of reinfection.

The difficulty in this problem has evidently been to accomplish the second object. If persons from other cottages have been allowed to work in the infested cottages, it is entirely possible that this has been the loophole.

No remedy effects a cure in the same length of time in all patients. Some have tougher skins and the remedy does not reach the organism so quickly, or perhaps some are more attractive to the itch mite, as has been demonstrated for the louse; but the more likely explanation is that some are not so thorough in applying the remedy. Potassium sulfide ointment will clear up most cases in twenty-four hours. A 10 per cent sulfur ointment will clear up most cases in four days; but there are exceptions. Sherwell (Remarks on the Treatment of Scabies, *J. Cutan. & Genito-Urin. Dis.* 17:494, 1899) advocated the use of washed sulfur alone for the treatment of scabies, the simplest of all methods; but he insisted on a full week's treatment and warned that some cases require nine days. He prefers it to the ointment method because it is cheap, easy to manage and not uncomfortable, avoiding the messy and evil smelling ointments. After the initial bath, hot water and toilet soap for children and thin skinned adults, sand soap (as sapolio) for thick skinned adults, the whole body is lightly rubbed with washed sulfur. A half teaspoon is enough for 1 person. The same amount is placed between the sheets of his bed, and the lower sheet is lightly shaken to disseminate it. This procedure should be repeated every second or third night. Baths and change of clothing may be taken as desired. Sherwell has never seen dermatitis from this procedure even in children, nor has it failed to cure. The physician must inspect the patient carefully after the final bath to make certain that all signs of activity of the itch mite have been eradicated.

The ordinary sulfur ointment treatment, 10 to 15 per cent for adults, 3 to 5 per cent for children, takes four days ordinarily. No bath or change of underwear is allowed during the treatment.

Those patients who have been pronounced cured must be strictly segregated and no contact allowed with any one who has not been examined and pronounced free from scabies. Certain persons tolerate the itch mite and show slight signs of its presence—even some who do not complain of itching—though this is rare. Attendants should be examined at intervals, and those waiting on the infected should not care for the cured. Bechet (Scabies: A Small Institutional Epidemic, with Interesting and Unusual Features, *Arch. Dermat. & Syph.* 16:51 [July] 1927) emphasizes the ease and rapidity with which the disease is spread.

Not only must the remedy be applied thoroughly to every spot on the body below the collar, but the clean-up of the clothing must be thorough, no single article being missed that has been worn next the skin of an infected person. The mites are not supposed to survive on the floor, but it will do no harm to sprinkle it with sulfur powder. This should be swept up before the cottage is filled with cured patients.

After the clean-up, measures to prevent contact with still infected persons must be maintained. The treated patients must be watched for recurrences, which occur sometimes after the

most careful inspection and call for a repetition of treatment; but the physician must carefully differentiate the cases of secondary dermatitis due to sulfur or to scratching. These must not be subjected to further treatment with sulfur, which commonly happens in such epidemics, but must receive soothing treatment, such as calamine liniment:

Gm. or Cc.

Calamine powder
Zinc oxide.....of each 8.0
Olive oil

Solution of calcium hydroxide.....of each 60.0

Mix and label: Dab on the affected part three times a day or oftener.

Continued itching is no proof that the treatment has failed, for the skin sometimes acquires the "habit" of itching, which persists after the original cause has ceased to operate.

Knowles (Scabies in Military and Civil Life, *THE JOURNAL*, Nov. 10, 1918, p. 1657) writes of his experience in the World War. Among 2,000 cases of skin disease there were 500 of scabies. He used 12 per cent precipitated sulfur in petrolatum. After the initial warm bath the soldier had to anoint himself under the eye of an officer, who saw that the job was done thoroughly. Each day for the next three days this was repeated and then, after another warm bath, the whole body was minutely inspected by an expert and if any signs of activity were found another course of four days was ordered. The treatment took place in a tent devoted to that purpose alone, all clothes were carefully disinfected and a separate bath was used by the infected men. Knowles remarks that the soldier's hands were involved less than he had been used to seeing in civilians but the penis was more markedly affected. The complications of scabies, furuncles, impetigo, folliculitis and ulcers occurred oftener in the military patient than in the one in civil life.

Despite the skepticism of Niles (Albuminuria in Association with Scabies, *Arch. Dermat. & Syph.* 38:19 [July] 1938) it will do no harm to examine the urine of children with scabies. Severe nephritis has been recorded, though this, as Niles suspects, may have been only coincidental.

POSSIBLE RESPIRATORY IRRITANT FROM COTTON DUST OR COTTON DYES

To the Editor:—What irritating substance or dye might be present in khaki-colored cotton now being made up for the government into coveralls and such garments? It is reported that the girls and cutters who handle this material suffer sore throats and an irritation of the nose. My patient has had a severe and persistent epistaxis.

Howard Kenneth Scatliff, M.D., Chicago.

ANSWER:—In dyeing military fabrics of a coarser nature, such as tent material and tarpaulins, in tan, brown, khaki or olive drab colors, mineral pigments ordinarily are utilized, embracing the salts of chromium and iron. For garment fabrics in these colors, sulfur brown dyes are used almost exclusively, of which there are more than seventy varieties, representing many chemical variations. Catechu, which is derived from acacia catechu, an Indian wood, may be employed. Further, redyeing by a variety of nonsulfur brown dyes to provide special shades or to overcome faulty dyeing with sulfur brown dyes is well known. It is possible that the minor irritation mentioned in the query may not be due to any cause at work, but, assuming the contrary, a number of theoretical opportunities for damage to the respiratory tract may be mentioned:

Ordinarily irritation from any dye is most commonly manifest as a dermatitis. The absence of dermatitis tends to but does not necessarily exclude dyes as the source of respiratory irritation. Failure to use sufficient sodium sulfide along with sulfur dyes may result in undissolved or reprecipitated sulfur brown, which may yield dye dust in the course of the fabrication of articles. Some sulfur brown dye dust may be irritating. On occasion, chromates may be used in connection with sulfur brown dyes, and, if a chromate dust is present, irritation of the nasal mucous membrane is a possibility. In case catechu is the dyestuff, allergens theoretically may exist.

It may be noted that cotton dust itself may be injurious to the respiratory tract, the irritation becoming chiefly manifest by asthma and chronic bronchitis. In England, compensation is provided for byssinosis, a dusty lung disease from cotton dust. Such compensation is limited to male workers in specified cotton mill operations, when the exposure has been for periods of twenty years or more. The limitation of compensation to men is not due to any nonsusceptibility of women but instead to the fact that only men are employed in the highly dusty operations involved. Occupational diseases from cotton dusts are described by Prausnitz (Investigations on Respiratory Dust Disease in Operatives in the Cotton Industry, London, His Majesty's Stationery Office, 1936). Compensation for byssinosis is described

in Report of the Departmental Committee on Compensation for Card Room Workers, London, His Majesty's Stationery Office, 1939, abstracted in the *Journal of Industrial Hygiene and Toxicology* 21:145, 1939, and mentioned in THE JOURNAL, Jan. 11, 1941, page 153. A full description of sulfur brown dyes may be found in a series of articles by A. E. Carr in the *Textile Colorist* beginning in 61:28, 1939. The dyeing of military fabrics is described by J. T. Gibbons in the *Textile World* 90:77 (Nov.) 1940.

The irritations mentioned in the query, if in fact of occupational source, are probably associated with cotton dust. Histamine, if present in the cotton, is of possible significance.

DERMATITIS FROM BUTANE OR BUTANE GASOLINE

To the Editor:—What is the toxicity of butane gas on the human body, both internally and externally? If possible, I should like to have the chemical analysis of this gas, with the name of each ingredient and the quantity of each, say, in 1 pint (475 cc.) of gas, or some such quantity. A person had a small quantity of this gas sprayed on his naked arm and hand. A severe irritation of the skin has developed, not only on the particular place on which the gas was sprayed but all over his body, even to the top of his head. He is positive that this gas caused the trouble, since the irritation developed within about twenty-four hours after it was sprayed on him. He has never had any cutaneous trouble of any kind before. In fact, he has always been perfectly healthy in every respect.

W. H. Peacock, M.D., Eastman, Ga.

ANSWER.—The query is not quite clear as to whether butane, C_4H_{10} , is meant or whether the so-called butane gasoline is meant.

Butane is a colorless, odorless gas, boiling at about 0 C., and is sold in special cylinders containing 12 to 114 pounds (5.4 to 51.7 Kg.). It is manufactured from refinery gases or obtained from natural gas in the process of making natural gasoline. As sold in the cylinders, it consists of 98 per cent normal butane, and the remaining 2 per cent is made up of propane, isobutane and some pentane. The standard specifications state that there shall not be more than 15 grains (1 Gm.) of organic sulfur in 100 cubic feet of the gas. The odor which may be present in commercial butane is due to traces of mercaptans. Butane is used as an enricher of illuminating gas, as a solvent with a low boiling point and as a refrigerant.

There are no reports of studies available on the direct toxicity of butane, but the petroleum solvents when taken into the body affect the blood and the nervous system. Acute poisoning by the petroleum solvents causes headache, blurred vision, mental confusion, dizziness, nausea and loss of consciousness. The effects of short, acute exposure rapidly wear off when the patient is taken into the open air.

The symptoms of chronic poisoning from long continued exposure to petroleum solvents are not characteristic. They consist of apathy, mental confusion, forgetfulness, tremors, muscular weakness, irritation of the air passages, bloody sputum, hemorrhages of the stomach, anemia, albuminuria and neuritis.

The lower the boiling point of a petroleum solvent, the more likely is a person exposed to it to show such symptoms, because the air is more quickly saturated.

Liquefied butane gas is likely to have a powerful irritating effect on the skin, because of its qualities as a powerful fat solvent as well as the fact that evaporation from the skin will result in freezing of the skin. The eruption would consist of erythema with pustules, vesicles and ulcers.

Butane gasoline is the name sometimes applied to natural gasoline or casing head naphtha. It is a liquid hydrocarbon mixture extracted from natural gas by compression, absorption in oil or adsorption in solids. It differs from straight run gasoline by its higher volatility and lower boiling range. It consists of the lower members of the paraffin series from propane to octane. Analyses of a representative sample of natural gasoline shows that it contains by volume about 20 per cent propanes and butanes, 39 per cent pentanes, 24 per cent hexanes, 12 per cent heptanes and 2 per cent absorption oil. A small proportion of aromatic hydrocarbons, such as benzene and toluene, may be present in some samples.

Natural gasoline, on account of its higher volatility, is more toxic and more irritating to the skin than straight run gasoline.

The patient probably not only suffered a dermatitis from the primary irritating effect of the gasoline but also became sensitized, so that other portions of his body, on which only minute portions of the gasoline may have fallen, became sites of allergic dermatitis.

APOMORPHINE AND ALCOHOLISM

To the Editor:—Will you please give particulars on the use of apomorphine in the treatment of alcoholism?

M.D., Illinois.

ANSWER.—Apomorphine is about as depressant as heroin, and hence the depressant action of both drugs, i. e. alcohol plus apomorphine, becomes additive and has been known to cause death through respiratory failure. It is much safer to use paraldehyde. Voegtlin (*The Treatment of Alcoholism by Establishing a Conditioned Reflex*, *Am. J. M. Sc.* 199:802 [June] 1940) has occasionally used apomorphine in order to cause nausea, when the other nauseating drugs used for the purpose of conditioning the person with habitual alcoholism against alcoholic drinks have failed. He advises caution in the use of apomorphine, since many patients treated with it suffer alarming syncope coupled with bradycardia at the onset of nausea.

BIFOCAL GLASSES

To the Editor:—The answer to the query on bifocal glasses (*The Journal*, March 15, p. 1186) should be supplemented. The occupation of the patient should always be considered when prescribing bifocal lenses. In many cases the usual 16 mm. segment will not be satisfactory. Many barbers require a large lower segment and a small upper portion. The same is true of mechanics. Sometimes mechanics get results by temporarily sliding their glasses down on the nose, not for the purpose of securing greater magnification, but to get the "add" out of the way so that they may look through the upper portion. The type of bifocal ordered depends on several factors, such as the financial status of the patient, the difference in strengths of the upper and lower portions of the lenses, the size of the segments, the difference in the refractions of the two eyes, and the contour of the face. The prescribing of bifocals is not always an easy matter, even after the correct refraction and amount of presbyopia have been determined. Then there are bifocals for myopes! Modern Ophthalmic Lenses and Optical Glass, by Theodore E. Obrig, is the best single volume on the subject. Good information can be obtained from a book on shop work published by Professional Press, Chicago. Bughee's Bifocals, though old, is an excellent treatise. Essentials of Modern Lens Theory, soon to be put out by the Continental Lens Company, will no doubt be a good work on the subject. All the larger wholesale optical companies send out literature on bifocals that can be studied by ophthalmologists to advantage. A wise eye physician consults a good optician frequently with regard to these problems.

J. J. Horton, M.D., New Orleans.

To the Editor:—There is a great deal of interest among presbyopes in general in bifocals and at times trifocal glasses. Frequently patients are dissatisfied with the lenses they receive and they would be even more dissatisfied if they were aware that, often, better combinations could be secured for them. Few general doctors and not all oculists know the last word in regard to this matter. For example, the surgeon often needs and can easily obtain a special segment. A satisfactory type is one with a large central "reading" section entirely surrounded with a distant segment so that he can see the operative field and can look to all sides for instruments and to note what is going on in the room. There are numerous modifications of this type of lens. A special glass is made for the artist and sculptor so that he can see his model, palette and canvas. The hunter and marksman often needs a segment near the bridge of the nose, and this can be obtained. The shoe clerk can obtain a lens so that he can read from the boxes above his head and at the same time can see patrons who enter the store. A large group need bifocal glasses focused beyond the usual reading distance, for example, the aviator, the carpenter, the laundress, the musician and the railroad engineer, to mention only a few. In his book "Modern Ophthalmic Lenses and Optical Glass" (Philadelphia, the Chilton Company Printing Division, 1935, pp. 261-271 inclusive) Theodore E. Obrig gives an excellent discussion of this subject with various illustrations. Any one interested or not entirely satisfied with the results he is receiving from bifocal or even trifocal glasses would be well repaid to read this article. There are perhaps other similar articles, but they are difficult to locate.

William B. Hubbard, M.D., Flint, Mich.

To the Editor:—In *The Journal*, March 15, page 1186, there appears a query concerning types of bifocals which is not as completely answered as it might be. The answer given deals almost entirely with the refraction of presbyopic patients, while the query concerns types of bifocals for people pursuing different kinds of work. Excellent references on this subject are:

Pascal, Joseph I.: Bifocal Lenses, *Arch. Ophth.* 24:553 (Sept.) 1940.

Crisp, W. H.: The Bifocal Age, *Am. J. Ophth.* 23:334 (March) 1940.

Olsho, Sidney L.: Vertical Prism Values in Commonly Used Bifocal Lenses, *Arch. Ophth.* 20:95 (July) 1938.

Help in choosing the type of bifocal for ordinary use may be had from the Bifocal Lens Prescription Analysis Chart published by Bausch and Lomb. The monocentric bifocals, discussed by Dr. Pascal in the reference mentioned, are made by the Uhlemann Optical Company of Chicago, who also will balance the prismatic effect in cases of anisometropia so that the prescribing physician does not have to make the difficult calculations. This company will also grind in the reading segment in any position desired by the prescribing physician. Carpenters, grocers, druggists and others who must see things at arm's length above their heads as well as in the usual reading areas are made comfortable by having ground into their lenses two segments for near work—one in the usual position and one above, leaving the middle for distant vision. Barbers and grocers are frequently helped by having the center of the lens ground for near work, leaving the periphery with the distance correction. Bookkeepers are helped by trifocals with an intermediate segment between the reading segment and the distance correction. The middle segment brings into focus material that may be scattered around a desk at arm's length.

THE DIAGNOSIS OF HYPOTHYROIDISM IN CHILDHOOD

LAWSON WILKINS, M.D.

AND

WALTER FLEISCHMANN, M.D.

BALTIMORE

When severe thyroid deficiency has existed over a considerable span of time during the early years of growth, it gives rise to the classic clinical pictures described as cretinism or as juvenile hypothyroidism, which are readily recognized. Many cretins, however, when seen in the first year or two of life, are less grotesquely abnormal, and on superficial inspection might be mistaken for fairly normal infants considerably younger than their actual age. In studying dwarfs of an older age, one finds almost innumerable variations and gradations from the broad, stocky build of the typical person with hypothyroidism to the slender, wiry, small-featured dwarf who presents no suggestion of thyroid deficiency.

Great differences of opinion have arisen as to what constitutes the signs of hypothyroidism in cases not presenting the frank, typical picture. In recent years there have been a lack of critical analysis and an excess of enthusiasm, so that the diagnosis of hypothyroidism has been made often on the finding of some one suggestive sign. If a child's eyes are widely spaced or his nose is flat or if he is mentally retarded or physically stunted, he may be diagnosed a cretin. In fact, almost any infant who is retarded in development or who is peculiar or ugly runs the chance of being branded as having hypothyroidism. Since most physicians are aware that epiphyseal ossification is delayed in hypothyroidism, roentgenograms of the bones are usually made. If retardation of osseous development is found, the physician considers that the diagnosis of hypothyroidism is proved. Dryness and coarseness of the skin and hair or a dull, phlegmatic disposition likewise may lead to uncritical diagnoses. The numerous variations in type among dwarfs give the endocrinologist opportunities for wide flights of fancy which alight on such diagnoses as thyropituitary, pituitarothyroid and thyrohypogonadal deficiencies, although there is often no real proof of either thyroid or pituitary deficiency.

The existence of "borderline" forms of hypothyroidism or of mixed endocrine disturbances should not be denied, nor should the therapeutic trial of thyroid be discouraged in doubtful cases. However, the limitations of our present knowledge should be frankly recognized and the need for diagnostic humility emphasized. It

seems worth while, therefore, to review and to attempt to evaluate the physical signs resulting from thyroid deficiency in childhood and to discuss some of the recent studies of the functional or biochemical changes.

CLASSIFICATION OF PHYSICAL SIGNS

In adults, many of the familiar physical signs of hypothyroidism depend on a lowered rate of metabolism and alterations in the circulation. In addition, abnormalities in chemical processes of the body are responsible for some of the characteristic changes in subcutaneous tissues, skin, hair and muscle to which the term myxedema has been applied. In childhood, thyroid deficiency gives rise to additional changes due to its influence on growth and development.

In table 1 are listed the most important signs which result from hypothyroidism during the period of growth. These signs have been divided into anatomic alterations in bodily structure and functional or physiologic alterations. The structural changes which are the most characteristic and the most constant are those caused by defective growth and development of the skeleton. These are stunted growth, infantile skeletal proportions, infantile naso-orbital configuration, retarded skeletal development, delayed and defective development of the teeth and epiphyseal dysgenesis. The changes in other structures of the body are less characteristic and are encountered much less constantly. Frequently the hair is entirely normal and there is little, if any, change in the skin. Thickening of subcutaneous tissues and soft parts such as the lips and tongue may be suggestive of the diagnosis when found; but such changes may not be advanced, and true myxedema is rarely as extreme as in the adult.

SKELETAL CHANGES

The skeletal changes must be considered in some detail.

Stunted Growth.—The rate of growth is invariably slowed in hypothyroidism. In a young cretin, who may be only 1 or 2 inches (2.5 or 5 cm.) below the average height, the dwarfing may not impress the observer. However, if a cretin remains untreated he lags more and more below the normal standards until stunting becomes apparent. During the juvenile period extreme degrees of hypothyroid dwarfism are encountered. On the other hand, if thyroid deficiency does not occur until later childhood—for example the tenth or twelfth year—the patient will have attained such a height before the cessation of growth that he cannot be classified as a dwarf.

Hypothyroidism is one of the most important causes of dwarfism. In the past five years we have studied 64 dwarfs in whom disease of bone and cardiac, renal, intestinal, hepatic and metabolic disorders could be excluded as etiologic factors. Among these, 16 patients (25 per cent) definitely had hypothyroidism. In the remainder, the cause of dwarfism could not be deter-

This work was supported by grants from the John and Mary R. Markle Foundation and from the Commonwealth Fund.

From the Department of Pediatrics, the Johns Hopkins University School of Medicine and the Harriet Lane Home, Johns Hopkins Hospital.

mined. They were presumed to have either pituitary insufficiency or "primordial dwarfism." In all but 1 of the 16 patients with hypothyroidism therapy with thyroid caused a rapid acceleration of growth, whereas similar doses of thyroid had little if any effect on the other types of dwarfism, as shown in figure 1. In the 1 patient who presented characteristic clinical and biochemical evidences of hypothyroidism but who showed no acceleration of growth on treatment with thyroid there was probably some other endocrine deficiency in addition to hypothyroidism. This case is discussed further at the end of the paper.

Skeletal Proportions.—The ratio of the upper and lower skeletal segments is determined as follows: The standing height is measured. The lower segment is measured from the top of the symphysis pubis to the floor. The length of the upper segment is found by subtracting the lower segment from the total height. According to the tables of Engelbach¹ the ratio of the upper to the lower segment is about 1.7 to 1.0 at birth. The lower segment, however, normally grows more rapidly than the upper, so that at the age of 5 years the ratio is 1.2 to 1.0 and at 10 or 11 years 1 to 1. The various opinions expressed by different authors concerning the skeletal proportions of children with hypothyroidism have been discussed by de Quervain and Wegelin.² It has been our experience that as the child with hypothyroidism grows older not only is growth retarded but the ratio of the skeletal segments remains that of a younger child, corresponding to the height age instead of the chronologic age.³ On the other hand, most dwarfs who do not have hypothyroidism attain the skeletal proportions approximately normal for their actual age, although this is not invariably true. This is illustrated in figure 2.

Naso-Orbital Configuration.—The characteristic facies so frequently seen in the child with hypothyroidism is due largely to the peculiar naso-orbital configuration. The bridge of the nose is flat and broad, causing the eyes to appear widely spaced, and the nose is short and undeveloped. De Quervain and Wegelin² have

TABLE 1.—Classification of Signs

Structural changes	
Skeleton	
Height—stunted	
Skeletal proportions, upper : lower segment—infantile	
Naso-orbital development—infantile	
Osseous development—retarded	
Dental development—retarded and defective	
Epiphyseal dysgenesis—frequently present	
Other structures	
Brain development—retarded

(Hair—variable)	
(Subcutaneous tissues—variable)	
Functional changes	
Physical and mental torpor	
Peripheral circulation poor—skin pale, grayish, cool	
Pulse rate × pulse pressure—decreased	
(Sweating—variable)	
Constipation	
Biochemical and metabolic changes	

attributed the abnormality to failure of growth at the spheno-occipital synchondrosis and disproportions in the development of the sphenoid bone. Dye and

Maughan⁴ have shown in experimental animals that the growth of endochondral bone is retarded while that of membranous bone is not. It seems to us that the hypothyroid facies is caused, at least partly, by the persistence of infantile characteristics, just as the proportions between the upper and lower skeletal segments

Fig. 1.—Comparison of the effect of thyroid treatment on a dwarf with hypothyroidism and on a dwarf showing a similar degree of osseous retardation but presenting no evidences of thyroid deficiency. Treatment caused a rapid acceleration of the rates of growth and osseous development in the hypothyroid patient but had little effect on the other dwarf.

remain infantile. The normal development of the features, and especially of the nose, is delayed, so that the child of 5 or 6 years with hypothyroidism often shows the naso-orbital conformation of an infant 1 or 2 years old.

Retardation of Osseous Development.—It has been known for many years that hypothyroidism always causes delay in the appearance of ossification in the cartilaginous centers. Treatment with thyroid causes an immediate acceleration in the rate of osseous development. We⁶ have found that by following the rate of osseous development during treatment one can determine whether an adequate dose of thyroid is being given.

In recent years, some clinicians unfortunately have jumped to the conclusions that the thyroid gland alone controls the ossification of the cartilages and that retardation of osseous development is pathognomonic of hypothyroidism. Diagnoses of so-called borderline hypothyroidism or of mixed thypituitary dwarfism have been based on this sign alone. We are convinced that this practice is fallacious. Endochondral ossification is at times definitely delayed in conditions which are not hypothyroid in origin. Among 50 dwarfs, in whom no evidences of thyroid deficiency were detected by means of any of the studies which we shall describe, 30 (60 per cent) showed delay of two to six years in appearance of the centers of ossification. In many instances the degree of retardation was as great as in patients with hypothyroidism. In these cases thyroid medication caused slight, if any, acceleration in the rate of osseous development, in contrast to the specific, rapid acceleration which occurs in patients with hypothyroidism. This is illustrated in figure 1.

3. Although the shortening of the lower extremities in hypothyroidism is largely attributable to the persistence of an infantile characteristic, shortening and deformity of the necks of the femurs may also contribute to it.

4. Dye, J. A., and Maughan, G. H.: The Thyroid Gland as a Growth-Promoting and Form-Determining Factor in the Development of the Animal Body, *Am. J. Anat.* 44: 331 (Nov.) 1929.

Defective Dental Development.—This subject cannot be discussed in detail in this paper. The development of the teeth is always retarded, and the delay is usually proportional to that in the endochondral ossification. In addition, the teeth which erupt during the period of thyroid deficiency are defective in structure and undergo early caries.

Epiphyseal Dysgenesis.—This is probably the most specific of all the anatomic changes which are found in hypothyroidism. It is due to a disorder of the cartilages of the epiphyses and round bones leading to irregularities in their subsequent ossification. Normally, ossification begins from a single small focus in the center of the cartilage and extends peripherally in an orderly manner. If thyroid deficiency exists during the period in which ossification normally occurs, the appearance of the deposition of calcium is considerably delayed, as we have already pointed out. When calcification finally occurs, it appears as multiple, small, irregular foci scattered over a considerable area of the cartilage. These grow larger and coalesce to form a single irregular center. According to the stage of the process, the roentgenogram may show multiple small centers of ossification or a single center which may appear either stippled, porous, fluffy or fragmented. Various stages in the ossification of the head of the femur in children with hypothyroidism are shown in figure 3. In the head of the femur the condition often cannot be differentiated in the roentgenogram from Perthes' disease. The two conditions, however, are entirely unlike in their pathogenesis. Perthes' disease is a destructive process involving an epiphysis which has previously been normally formed; in hypothyroidism there is an abnormality in the development of the cartilage and its conversion into bone. Although hypothyroid epiphyseal dysgenesis is observed most frequently and is most spectacular in the heads of the femurs and the navicular of the tarsus, it involves all the endochondral centers in which ossification normally

by some workers in a large proportion of patients with endemic cretinism. However, in reviewing serial roentgenograms of the bones of 25 children with hypothyroidism one of us⁶ found epiphyseal dysgenesis in all but 2 cases. In these 2 cases roentgenograms had been taken only at long intervals after treatment was begun.

Fig. 3.—Dysgenesis of the femoral epiphysis in cretins under treatment. Different stages in ossification. Case A illustrates the fact that dysgenesis may occur while the patient is under treatment with thyroid. A, cretin, first treated at the age of 6 years: A 1, first appearance of calcification two and one half months after beginning treatment; A 2, five and one half months after beginning treatment; A 3, twenty-two months after beginning treatment. B, cretin, first treated at the age of 8 years and 9 months: B 1, before treatment; B 2, seven and one half months after beginning treatment; B 3, twelve months after beginning treatment.

It was found not only that those centers which were already calcified before treatment with thyroid was begun were affected but also that those centers whose ossification had been delayed developed in the characteristically abnormal manner, even after the institution of therapy.

Retardation and Defect in Development of the Brain.—When thyroid deficiency occurs in the early years of life it causes delay in the development of the brain. If the condition remains untreated permanent damage may result, and there may be histologic changes in the brain cells which have been described by Lotmar.⁷ If treatment is instituted within the first year or two of life, permanent damage may at times be avoided and normal mental development may take place. If hypothyroidism does not occur until the later years of childhood, there may be no defect in the development of the brain and the intelligence quotient may be entirely normal, although the patient may be mentally sluggish and slow in response.

Diagnostic Significance of Structural Changes.—We have discussed so far the anatomic or structural changes brought about by hypothyroidism, especially those of the skeleton, and have pointed out that they are due principally to a retardation or a distortion of normal processes of development which occur during the growth period of early childhood. When all or most of these anatomic changes are combined, the clinical picture is usually unmistakable. However, some of these changes, for instance the dwarfing, the osseous retardation or the facial configuration, may occur in children who do not have hypothyroidism and may lead to mistaken

Fig. 2.—Diagram showing that the skeletal proportions of dwarfs with hypothyroidism correspond to the "height age," while those of other dwarfs correspond to the chronologic age.

occurs during the period in which the deficiency exists. It can be found if roentgenograms are taken frequently enough to show the earliest appearance of calcification. From the paucity of American literature on the subject one might suspect that the condition is relatively rare in sporadic cretinism, although it has been encountered

diagnoses. If hypothyroidism exists, one should find not only anatomic changes but also definite physiologic evidences of diminished thyroid function, such as physical and mental sluggishness, circulatory changes and

"borderline" forms of hypothyroidism or of mixed endocrine disturbances must depend on functional rather than structural changes.

FUNCTIONAL CHANGES

Mental sluggishness and physical inactivity are shown, to more or less degree, by all patients with hypothyroidism. The torpor and slow mental reactions characteristic of children with hypothyroidism are distinct from retarded or defective development of the brain. Thyroid therapy almost immediately causes the patient to become more alert and responsive; actual improvement in mental capacity occurs only gradually, and certain cerebral defects may be irreparable.

Diminution in the cardiac output and circulatory rate are constantly present. Clinically, however, the measurement of circulatory changes is difficult and unreliable in children. Although the pulse rate is usually decreased and the pulse pressure diminished, the difficulty of establishing true basal conditions and the absence of fixed norms make it impossible to apply the Read formula, which is the product of pulse rate and pulse pressure, to the diagnosis of hypothyroidism in children, as is sometimes done in adults. More reliable evidences of decreased peripheral circulation are a characteristic pale, grayish color of the cheeks and lips and a circulatory mottling of the skin. These are usually seen in children with hypothyroidism and, indeed, they are encountered with such regularity that one should hesitate to make a diagnosis of hypothyroidism in a child with bright, ruddy cheeks and lips. Whenever thyroid therapy is discontinued, the loss of color from the skin is usually the first evidence of a beginning relapse. A yellowish tinge of the skin due to the deposition of carotene is a more specific sign of hypothyroidism but is not found in all cases.

To devise more exact and objective methods of diagnosing thyroid deficiency the clinician has had to turn to laboratory methods. Although the study of the

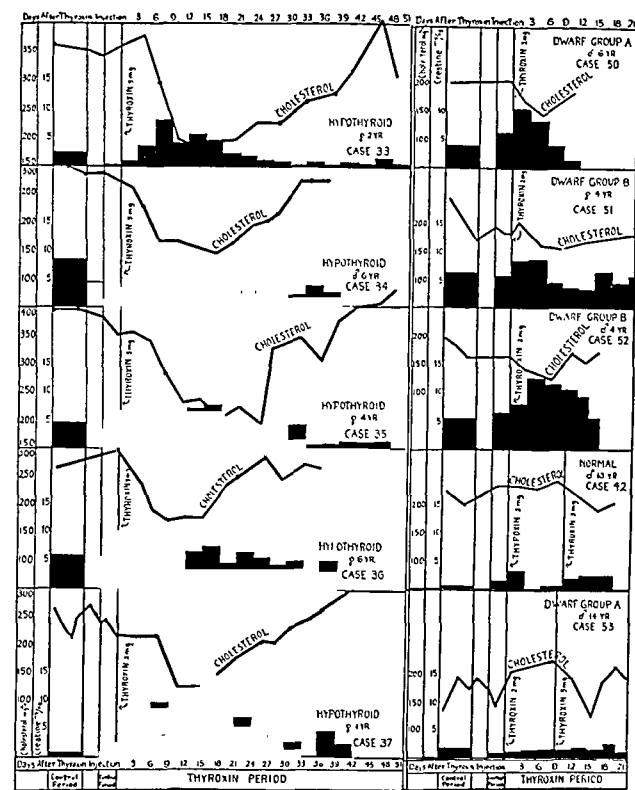

Fig. 4.—Response to a single dose of thyroxine. In the 5 patients with hypothyroidism (on the left side of the chart) there was a great and prolonged decrease in the serum cholesterol. In the 5 control patients presenting no evidences of hypothyroidism (on the right side of the chart) the decrease in the serum cholesterol was slight and transient. Dwarfs of group A showed noticeable retardation of osseous development, those of group B, normal osseous development.

metabolic and chemical abnormalities, which are discussed later.

The question now arises as to whether thyroid deficiency may occur during childhood without causing any of the characteristic structural changes. It is obvious that to cause such changes the deficiency must be present during the years of life in which the important developmental processes occur and that it must exist for a considerable period of time before any deviation from normal development becomes obvious. If hypothyroidism develops in a late period of childhood, for instance between the eighth and the twelfth year, when the more mature characteristics of the skeleton already have been attained, structural abnormalities are usually absent or of mild degree. If the deficiency is of only short duration, the deviation from normal may not be appreciable. In the first year of life the cretin is frequently hard to recognize by his appearance. Similarly, if hypothyroidism develops in a child at 6 years a number of years may elapse before there is sufficient deviation from normal development to suggest the diagnosis. Furthermore, if any thyroid treatment has been given during the important stages of development, all structural abnormalities may be prevented. Finally, it is theoretically possible that a mild degree of hypothyroidism might exist throughout childhood without causing characteristic anatomic changes. Since under the conditions mentioned thyroid deficiency might exist without any structural characteristics, the diagnosis of atypical or

metabolism of iodine might seem to be the most direct and specific approach to the problem, the technical difficulties of measuring the minute amounts of iodine present in the blood make it impractical for most laboratories. The methods of study which are readily avail-

able are the measurement of the basal metabolic rate, the serum cholesterol and the urinary excretion of creatine. We wish to discuss the recent work along these lines.

Fig. 6.—Serum cholesterol of children with hypothyroidism and of normal children before treatment, during treatment and after its withdrawal. Before treatment the concentration of cholesterol in children with hypothyroidism is often within the normal range. After treatment with thyroid is discontinued the cholesterol of children with hypothyroidism usually reaches high levels; that of normal children does not.

Basal Metabolism.—The measurement of the basal metabolic rate in young children or mentally subnormal children is unreliable, because of the difficulty in obtaining cooperation and establishing basal conditions. In only about one fourth of the children with hypothyroidism we⁸ have studied could the basal metabolic rate be determined satisfactorily. In these cases the basal metabolic rates were —25 per cent to —40 per cent when compared to the Boothby-Sandiford surface area standards. When compared to these standards the rates of many obese children who present no evidences of hypothyroidism are just as low. However, when a comparison is made to the Talbot⁹ height standards, children with hypothyroidism show definitely low metabolic rates, while obese children who do not have hypothyroidism have normal or even elevated rates. Occasionally we have seen children who have had a low basal metabolic rate even with the height standards and yet have presented no symptoms or signs whatever of thyroid deficiency. We do not believe that it is justifiable to base a diagnosis of hypothyroidism exclusively on the basal metabolic rate. The increasing popularity of the metabolism machine in the physician's office is becoming responsible for a growing number of ill considered diagnoses both in adult medicine and in pediatrics.

Serum Cholesterol and Creatine Excretion in Untreated Hypothyroid Children.—The serum cholesterol can be determined accurately and simply by proper chemical methods without the use of a special diet. The determination of the excretion of creatine requires that the patient be given a diet low in creatine and that the urine be collected quantitatively and examined daily over a period of one to two weeks. The cholesterol and creatine of untreated children with hypothyroidism have been discussed by Wilkins, Fleischmann and Block.⁸

The serum cholesterol in the majority of children with hypothyroidism is between 250 and 600 mg. per hundred cubic centimeters, compared to a range of 100 to 300 mg. per hundred cubic centimeters in normal children. In the child with hypothyroidism the concentration of cholesterol from time to time may fluctuate as much as 200 mg. per hundred cubic centimeters, whereas we have not encountered fluctuations greater than 80 mg. per hundred cubic centimeters in normal children. At times we have found the serum cholesterol as low as 150 mg. per hundred cubic centimeters in children with severe hypothyroidism. Since the ranges of cholesterol found in normal patients and those with hypothyroidism overlap, a cholesterol value below 300 or 325 mg. per hundred cubic centimeters does not exclude thyroid deficiency, but a concentration above this is suggestive of this diagnosis, if other causes of hypercholesteremia, such as diabetes, nephrosis or hepatic disease, are not present.

There is a tendency for the excretion of creatine to be low in the child with hypothyroidism, although it may be as high as 4 mg. per kilogram of body weight daily. There are, however, great differences in the excretion of creatine in normal children, varying from 0.5 to 8 mg. per kilogram of body weight daily. It is therefore impossible to differentiate the untreated child

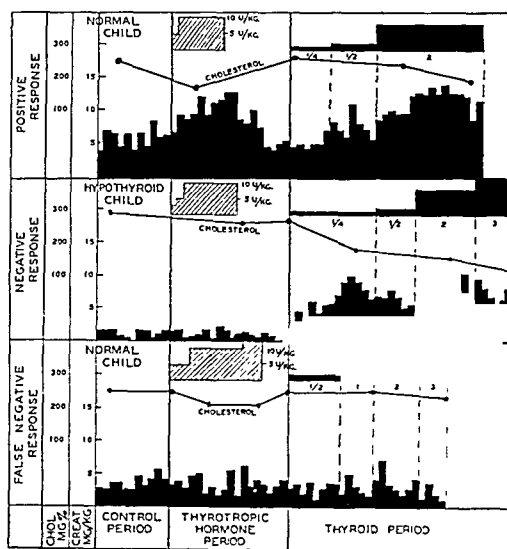

Fig. 7.—Response to thyrotropic hormone and to thyroid. The normal child having the "positive response" showed an increase of the excretion of creatine with thyrotropic hormone and with desiccated thyroid. The child with hypothyroidism having the "negative response" showed no increase of creatinuria with thyrotropic hormone but a definite increase with thyroid. The normal child having the "false negative response" showed no increase of creatinuria after the administration of either thyrotropic hormone or large doses of desiccated thyroid.

with hypothyroidism from the normal child on the basis of the excretion of creatine. Likewise, we have not found that the creatine tolerance test is of diagnostic value.

Sensitivity to a Standard Dose of Thyroxin Measured by the Effect on Serum Cholesterol and Urinary Creatinine.—It has been pointed out frequently that a small dose of thyroid or thyroxin has a remarkable effect on a person with thyroid deficiency, while the same dose has slight if any effect on a normal person. Means¹⁰

and his co-workers have emphasized that it is more important diagnostically to observe the effect on the basal metabolic rate of the administration of thyroid or the withdrawal of thyroid therapy than merely to measure the basal metabolic rate in the untreated patient. Since the determination of the basal metabolic rate is so unsatisfactory in children, Wilkins, Fleischmann and Block¹¹ decided to measure the serum cholesterol and the excretion of creatine in studying the effect of the administration and withdrawal of thyroid.

At first we attempted to compare the sensitivity of normal children and of those with hypothyroidism by giving small daily doses, $\frac{1}{4}$ grain (16 mg.) or $\frac{1}{2}$ grain (32 mg.), of desiccated thyroid by mouth. Great differences between the two groups were found, especially in the effect on the excretion of creatine. Later we found that a more satisfactory differentiation could be made by giving a single intramuscular dose of 2 mg. or 5 mg. of thyroxin. Figure 4 shows the results of these studies. In the child with hypothyroidism a single dose of thyroxin causes a noticeable decrease in the serum cholesterol. The effect lasts for a long period, from thirty to seventy days, usually about forty days, before the cholesterol returns to its previous high level. In the normal child the same dose of thyroxin causes only a slight and transient lowering of the level of cholesterol, usually lasting no longer than ten days. Even when the cholesterol concentration of the normal child and that of the child with hypothyroidism are not far different before injection, as in cases 37 and 42 (fig. 4), the responses to thyroxin differ sharply. The excretion of creatine does not show as great a difference between the two groups of children, because some normal children (case 52) show a decided increase in the excretion of creatine after the injection of thyroxin.

Effect of the Withdrawal of Thyroid Medication on the Serum Cholesterol.—In studying the effect of discontinuing thyroid medication we¹² have observed that the serum cholesterol usually rises to high levels, between 300 and 600 mg. per hundred cubic centimeters, within a period of eight to twelve weeks. A similar rise of cholesterol does not occur in a normal child if thyroid is given for a period and then discontinued.

This is illustrated in figure 5, in which are compared the cholesterol values of a normal child and one with hypothyroidism. Each had received large doses of thyroid for a long period. The concentration of cholesterol in each case was approximately 200 mg. per hundred cubic centimeters when thyroid was discontinued. The serum cholesterol of the child with hypothyroidism rose to 500 mg. at the end of six weeks; that of the normal child did not exceed 240 mg. It is of interest that after thyroid medication is discontinued the serum cholesterol in many cases reaches a higher concentration than is observed before treatment is first begun. This is illustrated in figure 6. The rise of cholesterol after the withdrawal of thyroid is of considerable practical diagnostic value. This is particularly true in children with hypothyroidism who previously have been treated elsewhere and who have lost all their stigmas of hypothyroidism. If the previous diagnosis is open to question, thyroid medication can be discontinued and the cholesterol observed over a period of eight to twelve weeks. A definite rise in cholesterol is often found long before characteristic clinical signs have returned.

Response to Thyrotropic Hormone.—The thyrotropic hormone of the pituitary gland stimulates the activity of the thyroid gland. By injecting this hormone and observing the effect on the excretion of creatine, the serum cholesterol and the basal metabolic rate, one might presumably determine whether the patient has a thyroid gland capable of functioning effectively. In studying this problem we¹³ found that the excretion of creatine was the most sensitive indicator of the effect of medication with thyroid, because in normal children the administration of thyroid usually causes a definite increase in the output of creatine but has little effect on the serum cholesterol. In making the test, the average daily output of creatine was determined over a control period of one to two weeks. Thyrotropic hor-

thyroid or of thyroxin was tested. This last step is essential in distinguishing "true negative" from "false negative" responses, as we shall explain later.

The three types of response, "positive," "negative" and "false negative," which were encountered are illustrated in figure 7, which shows studies made on 3 children—a dwarf with hypothyroidism, his normal twin sister and another normal control. In the first normal child the injection of thyrotropic hormone caused a definite increase in the excretion of creatine and a moderate decrease in the serum cholesterol. Desiccated thyroid caused a similar response. In the child with hypothyroidism, thyrotropic hormone had no effect on the creatine or cholesterol, while small doses of desiccated thyroid caused a decided increase in the output of creatine and a decrease in the serum cholesterol. This is a "true negative" response to the hormone, because the increased output of creatine with desiccated thyroid shows that the excretion of creatine is actually responsive to the effect of the thyroid. The other normal child showed the third type of response, which we have termed "false negative." In this case neither thyrotropic hormone nor the usual doses of thyroid had any effect on the excretion of creatine. Such a failure to respond to thyrotropic hormone cannot be interpreted as indicating that the thyroid gland is absent or unresponsive, because even the administration of thyroid caused no increase in the output of creatine.

Nine children with hypothyroidism whom we studied showed negative responses. Normal children and dwarfs presenting no evidences of thyroid deficiency usually gave positive responses, but a few showed the "false negative" response. Table 2 shows the results in 35 cases studied. It should be pointed out that under certain circumstances thyroid deficiency might be present in a patient having a positive response to thyrotropic hormone. This would occur if the gland was present and capable of stimulation but nevertheless was underfunctioning from some cause. We have encountered 1 such case not included in the table but discussed in the next section.

SUMMARY OF SPECIAL DIAGNOSTIC STUDIES

In table 3 are summarized the results of the special laboratory studies discussed. Exact criteria for the diagnosis of thyroid deficiency cannot yet be stated. We believe that the work discussed is only a beginning in the search for more specific and objective methods of measuring thyroid function. Among 42 children with hypothyroidism whom we have encountered in the last five years, most have presented characteristic clinical pictures of cretinism or of juvenile hypothyroidism. In such cases the elaborate biochemical studies described have served only to confirm diagnoses which were already fairly clearcut. During the same period we have seen 50 other dwarfs. In a few of these dwarfs of stocky build, the presence of noticeable retardation of osseous development and certain atypical anatomic features have suggested the possibility of the existence of a hypothyroid factor. In most of such cases the biochemical studies have failed to reveal evidences of thyroid deficiency. In other children coming under observation, studies such as we have described have been of value in excluding erroneous diagnoses of hypothyroidism based on the existence of a low basal metabolic rate or of a single anatomic peculiarity. Concerning the existence of mixed pituitary-thyroid deficiency we know little. So far we have studied only 1 patient who presented substantial evidence of a mixed deficiency. She

was a sexually immature girl aged 20 years. Biopsy demonstrated that her thyroid gland was present but atrophic. There were definite clinical and biochemical evidences of hypothyroidism. The injection of thyrotropic hormone apparently caused a biochemical response consisting of a fall in the cholesterol level from 369 to 221 mg. per hundred cubic centimeters. However, intensive thyroid therapy over a period of five years has brought about no sexual maturation and no appreciable acceleration in the rate of growth, in spite of the fact that the epiphysal lines are not closed. We think that this is the only case in which we have demonstrated a definite thyroid deficiency which may be secondary to a pituitary deficiency.

POSTMENOPAUSAL OSTEOPOROSIS

ITS CLINICAL FEATURES

FULLER ALBRIGHT, M.D.

PATRICIA H. SMITH, M.D.

AND

ANNA M. RICHARDSON, M.D.

BOSTON

Our object in this paper is to point out the existence of postmenopausal osteoporosis and to describe its clinical features. Some metabolic data showing the effects of therapy with estrogens and other agents are incorporated in other papers.¹

It will probably be well to start by explaining and defining the term "osteoporosis." Adult bone is normally subject to two continuous processes—formation and resorption. The mass of bone may be deficient either because resorption is too great (hyperparathyroidism with osteitis fibrosa generalisata) or because formation is too little (osteoporosis or osteomalacia). Formation of bone may be too little, furthermore, either because the osteoblasts do not lay down sufficient osseous matrix or because the matrix, once laid down, is not calcified. The former condition is osteoporosis; the latter, osteomalacia or rickets (fig. 1).

It is thought that stresses and strains are an important stimulus to osteoblastic activity and that the atrophy of disuse is due to a decrease of this stimulus. There is considerable evidence, furthermore, that the osteoblasts manufacture the enzyme phosphatase and that the serum phosphatase level (in the absence of hepatic disease) is an index to osteoblastic activity. An important clinical inference is based on these two suppositions. It may be stated as follows: In the presence of a rarefied skeleton, which is accordingly more subject to stresses and strains than the normal, the serum phosphatase level will be high unless the cause of the rarefaction is primary hypoplasia of the osteoblasts, i. e., osteoporosis. Hence a most important feature of osteoporosis is the absence of a raised phosphatase level.

Since osteoporosis is really not a disease of calcium metabolism, it is not surprising that the serum calcium and phosphorus levels are normal.^{2a} The same is not

This work was aided by a grant from the Committee for Research in Problems of Sex of the National Research Council.
From the Medical Service of the Massachusetts General Hospital and the Department of Medicine of Harvard Medical School.

2a. An exception to this statement occurs when young individuals have a large proportion of their skeleton abruptly immobilized by infantile paralysis or by a cast; under these circumstances one may encounter a hypercalcemia. This will be the subject of a separate communication.

always true of the urinary excretion of calcium and phosphorus, probably for the following reason: Since normally some of the calcium and phosphorus which is set free by the process of resorption of bone is used again for formation of bone, it follows that any curtailment of the latter process would increase the excretion of calcium and phosphorus in the urine. However, once the skeleton has become extremely depleted, the amount of calcium and phosphorus derived from resorption of bone will be small even though the amount of resorption per unit of skeleton remains constant. When this situation has arisen the urinary excretion of calcium and phosphorus will be normal or even low. Hence hypercalciuria and hyperphosphaturia disappear after the skeleton becomes demineralized in osteoporosis, in contradistinction to hyperparathyroidism, in which they persist regardless of the degree of decalcification.

REVIEW OF THE LITERATURE

We are by no means the first to suggest a connection between ovarian function and calcium metabolism. Lawrence and Ovidian² showed that there is more phosphorus in the blood stream of female than of male fowls and that still larger amounts of phosphorus are found in the blood of laying hens than of nonlaying hens. Riddle and Reinhart³ demonstrated that there is a definite rise in the blood level of calcium in pigeons at the time the eggs are ready to leave the ovary. Hughes, Titus and Smits⁴ showed an increase in serum calcium in laying hens. Macowan⁵ correlated the degree of rise of the serum calcium level in the hen with the size of the egg. Riddle and Dotti⁶ found in normal, hypophysectomized and thyroidectomized pigeons that the giving of follicle-stimulating hormone produces a rise in serum calcium; no similar rise was noted in castrate pigeons. Kyes and Potter⁷ noted that the long bones of female pigeons are solid while those of male pigeons are filled with marrow. Gardner and Pfeiffer⁸ gave estrogenic material to mice and noted that the marrow cavities were almost completely replaced by compact bone or by coarse bone spicules. Gardner and Pfeiffer⁸ showed that the giving of testosterone hinders this effect of estrogen on the skeletons of mice. Pfeiffer and Gardner⁹ found that administration of estrogen to pigeons causes hypercalcification of the long bones in both males and females and likewise raises the serum calcium level. Bach¹⁰ administered estrogen to female rats and found that there is an initial fall in the excretion of calcium followed by an increased excretion.

ETIOLOGY OF OSTEOPOROSIS

Whereas it is our primary object in this paper to point out that the postmenopausal state is a factor in osteoporosis, it might be well first to discuss other factors or possible causes of this condition. Factors which have been suggested are disuse, dietary deficiency, gastric hypoacidity, repeated pregnancies, long-standing thyrotoxicosis, senescence and Cushing's disease.

The atrophy of disuse is a well recognized clinical entity. It is most often produced by immobilization in

a plaster cast; it occurs in a limb which is affected by a flaccid paralysis. It is undoubtedly a factor in the generalized osteoporosis seen in older persons as their lives become more sedentary. An important differential clinical point is the fact that the atrophy of disuse seldom involves the skull, even when a patient is bedridden. This fact often helps to differentiate the condition from mild hyperparathyroidism but does not help to differentiate it from postmenopausal osteoporosis. In the series of cases studied in this paper (summarized in the accompanying table) an attempt has been made to call attention to any possible part played by the atrophy of disuse in the individual cases. In case 20, for example, the sequence of events may have been an automobile accident, the fracture of some vertebrae due to an adequate cause and the atrophy of other vertebrae due to immobilization. There is evidence, however, that atrophy due to forced disuse is greater in patients after the menopause than before (case 34).

We do not have any definite convictions as to what part diet may or may not play in the causation of osteoporosis. Diet, of course, has everything to do with osteomalacia, but that is an entirely different disease. There are at least three ways in which diet might be thought to play a part. Some investigators apparently believe that the increased availability of calcium and phosphorus in the system as the result of a diet rich in these substances is a stimulus to osteoblastic activity and that a decreased availability leads to decreased osteoblastic activity. As far as we are aware, there is no evidence to support this point of view. If the amount of calcium and phosphorus in the diet has any effect on the causation of osteoporosis, it seems unlikely that it is by such a mechanism. A second possibility is that an increased availability of calcium and phosphorus in the system because of the diet would decrease the amount of resorption of bone. If such were the case, any primary hypofunction of the osteoblasts would be partially offset by the decreased resorption and the patient would be benefited. Such a hypothesis would explain the apparently beneficial effect obtained by some investigators¹¹ in the treatment of patients with osteoporosis with diets high in calcium and phosphorus and large amounts of vitamin D. We favor the second possibility; it is in keeping with the concept which has been frequently emphasized from this clinic that a diet high in calcium and phosphates prevents the decalcification due to hyperparathyroidism. Finally, as a third possibility, a diet inadequate in protein might lead to a negative nitrogen balance, and this in turn might make it impossible for the osteoblasts to lay down the necessary organic matrix, which is the first step in the formation of bone. We believe that some of the osteopathies which have been attributed to a lack of calcium and phosphorus in the diet are really due to protein starvation.

In the table it will be noted that there were few abnormalities in the diet in this group of cases, and we are inclined to minimize the effect of diet.

Before the part played by diet is passed by, however, it might be of interest to discuss two recent papers by Prof. E. Meulengracht,¹² of Copenhagen. This author uses the terms osteomalacia and osteoporosis interchangeably. The cases described,

however, are cases of what would be diagnosed in our clinic as "osteoporosis." The patients had normal serum calcium, phosphorus and phosphatase values. The disease was confined mostly to the spines. The first of these papers had to do with 6 patients in whom Meulengracht attributed the condition to faulty diet and the second paper with 9 patients in whom he attributed the condition to hypochylia, not necessarily achylia. Of these 15 patients, 11 were women who had passed through the menopause, and, in our opinion, they were probably suffering from postmenopausal osteoporosis. The osteoporosis of 1 of the men (case I) could be attributed just as well to the atrophy of disuse. The first symptom was a nocturnal epileptic attack which led to paralysis of the legs and caused the patient to be bedridden for a few weeks. It is common to fracture a perfectly normal vertebra in an epileptic attack,¹³ and the immobilization due to the fracture would then lead to osteoporosis. The osteoporosis of the second male patient (case III) was less convincing than that of the female patients. Thus the statement was made that "there was calcium deficiency of the vertebrae, but not very pronounced." The third male patient (case XIV) entered the hospital with severe scurvy. The vitamin C deficiency in itself might have been a factor in the osseous disease. The roentgenograms did show definitely increased radiability of the vertebrae. The statement was made, however, that the anterior longitudinal ligaments were considerably ossified. It would be our opinion that this indicated that the patient was suffering from or had suffered from spondylitis, which is probably akin to rheumatoid arthritis, and that the atrophy was due to this condition. We have recently studied a similar case in which there were increased radiability of the vertebrae and calcification of the anterior longitudinal ligaments. This case was not included in the series here analyzed because there seemed to be a definite local cause for the disease of the bone. Meulengracht's case XV (the fourth male patient) was complicated. There was a twenty year history of dyspepsia at the end of which time a pyloric resection was done for pyloric stenosis due to a gastric ulcer. There was increased radiability of the spine, which almost surely was related to the gastrointestinal history. It would appear to us, therefore, that of these 15 cases 11 were probably postmenopausal osteoporosis and that the remaining 4 in men could easily be explained on other grounds. That diet or gastric hypoacidity was an important factor seems inadequately established although by no means disproved. The possibility remains that the prerequisites for the development of the disease are the postmenopausal state plus an inadequate diet.

Repeated pregnancies probably cause a drain on the body's supply of calcium and constitute a well known factor in the causation of osteomalacia. However, it is unlikely that pregnancy would have any effect on the causation of osteoporosis. It was considered, however, of interest to list in the table the number of pregnancies in the various cases.

There is an increased excretion of calcium in the urine and feces in cases of thyrotoxicosis.¹⁴ Williams

and Morgan¹⁵ presented some evidence that long-standing thyrotoxicosis leads to increased radiability of the skeleton.

It is perhaps of interest that all of their 7 patients were women, and, as was pointed out by them, that

Fig. 1.—Schematic diagrams to show the authors' conception of differences among normal function of bone, osteoporosis, hyperparathyroidism with osteitis fibrosa generalisata and osteomalacia. A, body limits; B, body fluids; C, body serum, a compartment of fluid easy to tap for analysis; D, mass of bone with two surfaces, one at which bone is being resorbed and one at which it is being laid down; E, arrow indicating by its size the rate of resorption of calcium and phosphorus; F, osteoclast; G, rate of deposition of calcium and phosphorus; H, osteoblast laying down osteoid (I); J, calcium and phosphorus entering the body from the gastrointestinal tract; K, calcium and phosphorus leaving the body by the kidneys or by other exits; L, syringe obtaining serum for analysis, and M, blood values (n = normal, + = high and — = low).

A. Normal.—Note that the calcium and phosphorus going into bone equals that coming out of bone and that part of that which comes out goes back in.

B. Osteoporosis.—Note decreases in the mass of bone (D); primary hypoplasia of osteoblasts (H₁); decreased deposition of osteoid (I₁); decreased deposition of calcium and phosphorus (G₁); increased excretion of calcium and phosphorus (K₁), and normal blood values (M₁).

C. Osteomalacia.—Note decreased mass of bone (D₂); hyperplasia of osteoblasts because of increased stresses and strains (H₂); increased deposition of osteoid which is inadequately calcified because of serum calcium and phosphorus values; decreased deposition of calcium and phosphorus (G₂); primary difficulty in absorbing calcium and phosphorus from the gastrointestinal tract (J₂); and abnormal blood values (calcium normal or low, phosphorus low and phosphatase high).

D. Osteitis Fibrosa Generalisata Complicating Hyperparathyroidism.—Note increased excretion of calcium and phosphorus in the urine (K₃); increased resorption of calcium and phosphorus (E₃); increase of osteoclasts (F₃); decreased mass of bone (D₃); increased formation of bone by osteoblasts (I₃) because of increased stresses and strains; increased deposition of calcium and phosphorus (G₃) because serum is not undersaturated in respect to calcium phosphate (i. e. the serum calcium level is sufficiently high almost to offset the low serum phosphorus content), and the high phosphatase level (M₃).

5 were over the age of 50. We are not aware that histologic studies have been done on osseous material from patients with thyrotoxicosis, and the nature of the disease of bone is still unknown. Patients 38, 39 and 40¹⁶ in the series here reported had a history of thyrotoxicosis. The osseous changes were similar from

16. Case 40 was previously reported as case 383 by J. H. Means (The Thyroid and Its Diseases, Philadelphia, J. B. Lippincott Company, 1937).

Summary of Clinical Observations

Identification		Age and Time Data			Etiology			Symptomatology		
		Age and Date When Seen	Age at Menopause	Interval Between Menopause and First Symptom, Years	Diet	Number of Pregnancies	Evidence for Disuse Atrophy as a Factor	First Symptom and Precipitating Incident	Duration of Symptoms *	Disability
AFTER PHYSIOLOGIC MENOPAUSE										
1	Miss L. M.	65 1935	47	10	Generally poor; little milk until 7 yrs. before; 1 glass daily since	0	0	Fractured surgical neck of humerus in a fall	1 day	Fracture not united
2	Mrs. F. T.	65 1931	50	14	Drank milk	2	Inactive since fracture of 2 mos. duration; cast for 2 mos., then limited activity	Spontaneous fracture of both bones of lower right leg, without adequate trauma	1½	Unable to do housework for 2 years
3	Miss P. S.	65 1937	61	9	Little milk; meat once daily	0	Change from active to sedentary occupation	Spine "gave way" while pushing boat off dock; pain in lower back since	5	Feels insecure; cane, corset and brace
4	Miss E. F.	65 1934	35	31	½ pint milk daily for 10 yrs. before menopause; for next 10 yrs. 1 pint daily as beverage; once daily all her life	0	0	Pain in right iliac region following jolt in car	3 mos.	..
5	Mrs. D. S.	64 1932	40	24	No data	5	Limited activity	Pain in legs with increasing weakness	4 mos.	Insecure
6	Mrs. M. M.	63 1934	52	9	Rarely ate meat; no milk	1	Bedridden for 3 wks. 1 yr. before seen; back strapped for 6 mos. thereafter	Continuous burning pain in back, arms and legs since "throwing brake" on car	2	Requires rest periods; corset and brace
7	Mrs. W. R.	63 1935	54	8	Drank no milk	5	0	Onset of severe pain in back while pounding tacks in footstool; had both weakness and pain on motion thereafter	1	Limited activity; corset and brace
8	Mrs. I. E.	63 1935	38	10	See "Comment"			Radiating pain in abdomen and back, thought to be arthritis; no precipitating incident	3 mos.	Corset and brace
9	Miss I. M.	62 1937	Some milk as a beverage for 5 yrs.	0	Cast for ankle 3 mos.; crutches for 2 mos. in addition	Slipped on steps and fractured ankle; later had pain in hips and lower part of back, especially on lying down	2	Walking painful; especially climbing stairs
10	Mrs. H. K.	62 1937	50	11	Milk in cooking, not as beverage; occasionally cottage cheese	4	Immobilization, 16 wks.	Fractured hip from fall on rug	1½	Fracture not united
11	Mrs. A. McD.	61 1939	47	13	1 glass to 1 pint milk daily as beverage and in cooking; no cottage cheese	0	0	Onset of sudden severe pain in right flank while sitting in church; numbness in left leg	5 mos.	Requires rest periods, care; corset and brace
12	Mrs. E. H.	60 1938	45	15	Little meat; a few vegetables and some butter; carbohydrates	3	0	Sudden pain in back on leaning forward	2 mos.	0
13	Mrs. E. P.	60 1939	53	6	Whole milk in cooking; cream in coffee and on cereal; no cottage cheese	..	Bedridden since injury	Pain in back since fall down six steps; landing in sitting position	1½	Bed most of the time; cane, corset and brace
14	Mrs. S. F.	59 1933	49	9	Always drank 1 glass of milk daily	2	0	Onset of sudden severe pain in left scapula while stooping forward	1	Generalized weakness
15	Mrs. F. H.	59 1933	48	10	Used milk in cooking only; ate meat and vegetables	5	0	Hit by trolley car; pain in back thereafter	1	..
16	Mrs. I. H.	59 1936	38	9	No milk	6	0	Fell on ice; entered hospital at once for pain in back	1 day	Pain and spasm; corset and brace
17	Mrs. R. C.	59 1936	38	14	No milk or cheese	2	0	Experienced "crack" in back on bending over; backache thereafter	7	Corset and brace
18	Mrs. D. G.	58 1932	50	7	No milk	2	Cast for 2 mos.; bedridden for 6 mos. because of fractured hip	Fell from street car and fractured hip; nonunion of fracture	9 mos.	Limp due to short left leg; corset and brace
19	Miss J. M.	57 1933	53	4	Moderate use of milk before menopause	0	0	Bent over and suffered sudden pain in back which persisted	1 wk.	Walks with cane
20	Miss M. M.	56 1937	48	7	No milk	0	0	Severe pain in left leg after fall on ice	1	Difficulty in walking; weakness; corset and brace
21	Mrs. M. W.	55 1934	44	11	No data	0	0	Fell on steps, striking knee and spine; severe back pain	1 day	0
22	Miss S. McA.	55 1939	45	7	Ate meat twice daily 10 yrs. before menopause, cottage cheese occasionally; 1 glass milk daily after menopause and more cheese in diet	0	Cast for 7 wks. for injury of back	Pain in back after severe jolt in car	3	Corset and brace

* The duration of symptoms is in years unless stated otherwise.

AFTER ARTIFICIAL MENOPAUSE										
28	Mrs. M. S.	64 1940	41	14	2 glasses of milk a week as beverage	8	0	Shortening stature and rounding of back, with pain	9	Corset and brace
29	Mrs. M. G.	63 1936	33	28	No milk	6	..	Severe pain in lower part of back on closing upper sash of window	2	Lumbosacral portion of spine rigid
30	Miss A. T.	62 1935	43	19	No milk, meat or eggs	0	Has used crutches or cane since fracture of femur at 56	Severe back pain on motion since fall backward after tripping over rug	1 mo.	..
31	Miss E. S.	60 1936	32	21	Moderate amount of milk on cereal and in cooking; has eaten meat and varied diet all her life	0	Almost bedridden for 7 yrs; cannot walk alone	7	Depends on crutches; teaches dress design sitting
32	Mrs. A. R.	58 1935	45	10	1 glass milk daily as beverage; milk in cooking; cheese frequently; high calcium and protein diet since 53	5	Changed to sedentary work at 54	Onset of severe pain between the shoulders while trying to raise upper sash of a window	4	Cautious activity with corset and brace
33	Miss I. S.	53 1938	52	10 mos.	No milk	0	0	Pain in knees, hips and lower part of back; pain in left shoulder	1 day	0
34	Miss T. M.	51 1938	33	13	Drinks little milk	0	Confined to bed 3 mos. at 33 after oophorectomy	Turned ankle and injured knee cartilage; pain and swelling of knee	5	Crutches, plaster cast on right knee
35	Mrs. C. DeN.	51 1940	36	13	A little milk used in coffee only before menopause; meat usually once daily	3	0	Pain in left sacro-iliac region	2	Limitation of motion on bending backward
36	Mrs. M. B.	49 1938	28	14	Always 1 glass milk daily as beverage; occasionally cheese; always ate meat and vegetables; 1 pint milk daily since 1938	2	..	Sudden onset of pain in right shoulder and limitation of motion while driving automobile	2	Limited shoulder motion
37	Mrs. F. F.	42 1938	41	9 mos.	Daily milk 1924-1927; occasionally cheese	0	..	Gradual onset of back pain with increasing dorsal kyphosis; no precipitating cause	1	Active but uses corset and brace
COMPLICATED BY HYPERTHYROIDISM										
38	Mrs. A. L.	60 1932	50	..	No use of milk; occasional use of cheese all her life	4	..	Gradual onset; no symptoms attributable to osteoporosis	..	Lateral curvature; corset and brace
39	Mrs. H. R.	60 1936	45	..	2 glasses milk a day up to age 20; 4-6 oz. cottage cheese; since menopause, 1 glass milk as beverage, 1 oz. cottage cheese daily	1	..	Symptoms of osteoporosis not complained of; marked by other symptoms	..	Limited activity; corset and brace
40 ¹⁰	Mrs. B. S.	50 1931	Low calcium and protein diet until 50, when first under care	0	..	Sudden onset of knife-like pain in lumbar region while driving automobile	3 mos.	Little activity; corset and brace
MEN										
41	Mr. V. S.	60 1935	No milk	..	Changed to sedentary occupation 8 yrs. before	Symptoms probably not attributable to osteoporosis	2	Legs weak; uses cane; spastic gait
42	Mr. H. B.	48 1939	No milk or cheese	Experienced sharp pain and heard snap in region of twelfth dorsal vertebra after twist of back while playing golf	3	Amble along with cane; bent over; wears brace

a clinical point of view to those seen in typical postmenopausal osteoporosis.

All 3 of these patients were women who had experienced the menopause. It is believed that the menopause alone could have accounted for all the osseous changes. Whether the thyrotoxicosis was an associated factor or the only factor cannot be stated.

Fig. 2 (case 13 in table).—Crushed vertebra.

The bones, like so many other tissues (skin, hair, elastic tissue) atrophy in old age in both sexes. Fracture of the hips of very old people is a common clinical manifestation of this process. This atrophy is osteoporosis and is generally designated "senile osteoporosis." In the group of cases here reported we were not concerned with senile osteoporosis, and we have arbitrarily omitted all cases of osteoporosis occurring after the age of 65.

Since the osteoporosis of Cushing's syndrome is probably closely related to that occurring after the menopause, it will be discussed after menopausal osteoporosis.

CLINICAL CHARACTERISTICS OF POSTMENOPAUSAL OSTEOPOROSIS

Some clinical data on 42 cases of osteoporosis are tabulated. The chief argument for the existence of postmenopausal osteoporosis, other than the beneficial effects of estrogen on the calcium metabolism¹⁷ in these cases, is the frequency with which osteoporosis occurs in women after the menopause. Thus the 42 cases listed in the table represent all the cases of generalized osteoporosis without an obvious cause, such as infantile paralysis, which have come to our attention or which we have been able to find in the hospital diagnosis index since the year 1931. Patients over 65 years of age have been excluded because of the possibility of senescence as a factor (as noted previously). By the term "generalized osteoporosis" it is not implied that the

osteoporosis involves all the bones of the body but that it is not confined to a local region such as one vertebra or one extremity.

Of the 42 patients, 40 were women who had passed the menopause. Two were men (cases 41 and 42); no explanation for the osteoporosis of these was apparent. In no instance did the condition occur in women before the menopause. That this is not just a matter of age is not entirely disposed of by the 10 women in whom osteoporosis occurred with artificial menopause, since the ages of these 10 women were not strikingly different from those in the group of patients with physiologic menopause. Case 36 was interesting, however, in this connection in that the patient underwent an artificial menopause at the age of 28 and her symptoms developed at the age of 42. The average time of onset of symptoms after the menopause was nine and one-half years in the 27 cases of uncomplicated physiologic menopause and thirteen and two-fifths years in the 10 cases of artificial menopause. The difference between these two values is not statistically significant.

It will be seen from the table that postmenopausal osteoporosis has a predilection for the spine and the pelvis; long bones are involved only in the cases of more severe involvement. The skull is notable for its lack of involvement; this is an important point in differentiating postmenopausal osteoporosis from hyperparathyroidism, since in the latter condition the skull is one of the first bones to show roentgen evidence of involvement. The spinal lesions consisted of fractured or crushed vertebrae (fig. 2), the so-called fish vertebrae (fig. 3) and herniation of the nucleus pulposus through the end plates of the vertebrae, or "schmorlsche knoetchen" (fig. 4).

The commonest syndrome is that due to a vertebral lesion. Essentially the same story keeps repeating itself: A woman, about ten years after the menopause, receives a minor jolt (by going over a bump in an automobile, for example); she experiences a pain in the back; finally she has a roentgen examination which reveals the condition. This examination may be made for some other malady, and in these instances there may be no symptoms. Since, as previously discussed, there is an increased excretion of calcium in the urine in the early stages of osteoporosis, it is not surprising that some patients with this condition have urinary calculi. Patient 7,

Fig. 3 (case 24 in table).—So-called fish vertebra. Note that intervertebral disks have expanded into vertebrae, converting them into biconcave disks.

17. Albright, Fuller, and Bloomberg, Esther, to be published.

for example, noted the passing of gravel on frequent occasions for one year after the menopause, which occurred at the age of 54. There were then no further symptoms until nine years later, when she experienced a severe pain in the back while pounding some tacks into a footstool. Patients 3, 4, 10 and 26 also had histories of urinary calculi (as did patient 42, one of the two men in the series). On physical examination patients with osteoporosis tend to show their age prematurely. Their skin is noticeably thin, this condition suggesting that the atrophy is more widespread than just in the bone matrix.

CUSHING'S DISEASE

The pathologic condition of bone associated with Cushing's disease is osteoporosis and has many of the clinical characteristics of postmenopausal osteoporosis. We have studied 5 patients (2 with adrenal cancers and 3 without) who will be the subject of a separate report.¹⁸ In this disease there is a decrease or an absence of the formation of estrogen and, in addition, an increase in urinary androgens.¹⁹ It is interesting that Gardner and Pfeiffer²⁰ have found that testosterone inhibits the effect of estrogen on the formation of bone in doves, and it may be that the excessive androgens in Cushing's disease cause the osteoporosis to be so severe. It may be partly for this reason, too, that we have found estrogen ineffective in Cushing's disease in producing a positive calcium balance.¹⁸ However, in our opinion,²¹ the most important factor in the causation of the osteoporosis in Cushing's disease is the negative nitrogen balance due to an increased conversion of protein into sugars.

MENOPAUSAL OSTEOPOROSIS COMPLICATED BY PAGET'S DISEASE

Case 23 in the table is of much theoretical interest in that postmenopausal osteoporosis was superimposed on Paget's disease. The net result was what one would have expected. It is the belief of one of us (F. A.) from unpublished data that the sequence of events in Paget's disease is (a) destruction of bone due to an unknown cause, (b) osteoblastic stimulation due to increased stresses and strains and (c) overgrowth of bone and increase of the serum phosphatase level as a result of osteoblastic stimulation. Thus if Paget's disease were superimposed on osteoporosis one would expect steps b and c to be missing because of the primary hypofunction of the osteoblasts. Patient 23 had a normal phosphatase level, and the roentgenogram showed any evidence of overgrowth of bone in the area of Paget's disease to be lacking.

Another example of the two conditions occurring in the same patient was recently seen (Mrs. M. L.). The patient was 62 years of age and had had a physiologic menopause at the age of 44. She had been under treatment for pernicious anemia for four years. She had advanced atrophy of the skin and had had a vulvectomy for kraurosis. There was advanced osteoporosis of the

spine and pelvis, but no fractures of the vertebrae. The extraordinary feature of the case, however, was the patient's skull. The whole top of the head was flat and soft, and the pulsations of the brain could be felt and seen. The roentgenogram showed extreme decalcification of the skull due to Paget's disease. Here again steps b and c were left out, in all probability because

Fig. 4 (case 13 in table).—Herniation of nucleus pulposus through end plate of vertebra ("schmorlische knoetchen").

of superimposed postmenopausal osteoporosis. The patient's serum calcium was 9 mg., serum phosphorus 3.2 mg. and serum phosphatase 15.7 and 21.9 Bodansky units per hundred cubic centimeters.

POSTMENOPAUSAL OSTEOPOROSIS COMPLICATED BY HYPERPARATHYROIDISM

In a previous publication from this clinic²² a case was described in which the combination of osteoporosis with hyperparathyroidism was present. Hyperparathyroidism when it does cause disease of bone does so by increasing destruction of bone. Normally this process is partially met by increased repair of bone due to osteoblastic activity, and the phosphatase level is high. If the condition is complicated by osteoporosis the osseous changes will be out of proportion to the degree and the duration of the hyperparathyroidism, and the phosphatase level will be unexpectedly low for the degree of decalcification.

SUMMARY AND CONCLUSIONS

1. Calcium deficiencies of the skeleton due to metabolic disorders are divided into those due to increased resorption of bone and those due to decreased formation of bone; deficiencies due to decreased formation of bone are further subdivided into those in which calcium is not deposited in osteoid tissue (osteomalacia or rickets) and those in which the osteoblasts are primarily deficient in laying down osteoid tissue; this is osteoporosis.

21. Fraser, R.; Forbes, A. P.; Albright, Fuller; Sulkowitch, H. W., and Reifenstein, E. C., Jr.: Colorimetric Estimation of "Seventeen Ketosteroids" in Urine: A Survey of the Use of This Test in Endocrine Investigation, Diagnosis and Therapy, *J. Clin. Endocrinol.*, to be published.

2. Emphasis is placed on the fact that osteoporosis is not a disorder of calcium metabolism but rather an atrophy of the bone matrix.

3. Factors in the causation of osteoporosis are disuse and senescence; that faulty diet is a factor, in our opinion, has not been established.

4. Because of the constant tendency of osteoporosis to occur in women after the menopause and the beneficial effect of estrogen therapy on the retention of calcium in this condition, we believe that the postmenopausal state is the most common etiologic factor.

5. Of 42 patients under the age of 65 with generalized osteoporosis, 40 were women who had gone through the menopause (physiologic 30 cases, artificial 10 cases); only 2 were men; there were no cases in women before the menopause.

6. Three of the 42 patients had had thyrotoxicosis; whether this had been a factor in the causation of the disease it is impossible to state.

7. Postmenopausal osteoporosis has a predilection to involve the spine and the pelvis; the long bones are less likely to be involved; the skull, in contrast to osteitis fibrosa generalisata, is almost never involved.

8. There is considerable evidence that patients with postmenopausal osteoporosis have a tendency to atrophy of other tissues, notably the skin.

9. In 2 cases postmenopausal osteoporosis was complicated by superimposed Paget's disease; the modification of the latter disease by the former is noteworthy.

10. One case of postmenopausal osteoporosis was complicated by superimposed hyperparathyroidism; the latter disease was modified by the former.

TREATMENT OF DEMENTIA PARALYTICA

A FIVE YEAR COMPARATIVE STUDY OF ARTIFICIAL
FEVER THERAPY AND THERAPEUTIC MALARIA
IN TWO HUNDRED AND THIRTY-TWO CASES

JACK R. EWALT, M.D.

AND

FRANKLIN G. EBAUGH, M.D.

DENVER

This is a report of a five year study comparing the therapeutic efficiency of artificial fever therapy and of therapeutic malaria. The preliminary report of this study was made in 1936.¹ There is nothing unique in the use of either malarial therapy or artificial fever, the former having been advocated by Wagner von Jauregg's original report in 1917 and the latter by Neymann and Osborne² in 1929. For reasons not entirely clear to us certain clinics treating patients with neurosyphilis have been skeptical of the therapeutic value of artificial fever in this neuropsychiatric disorder. Because of this apparent prejudice against a new method we felt it wise to observe a series of patients, taking alternate patients in the series for treatment with each method. Patients were assigned to the artificial fever or malaria series in alternation as they were admitted to the Colorado

Psychopathic Hospital and Clinic, that is, patient 1 went to the malaria series, patient 2 to the artificial fever series and so on. The postfever care has been according to the same plan in all cases from both series and has consisted of intensive chemotherapy with tryparsamide, neoarsphenamine and bismuth compounds according to the plan given in the accompanying outline.

Since the inauguration of this study there have been numerous reports³ advocating the use of artificial fever therapy in the treatment of neurosyphilis and others reporting on the present status of therapeutic malaria.⁴ The best statistical analysis of a comparison of the therapeutic efficiency of the two methods used independently has been made by the Cooperative Clinic Group.⁵ The historical background of this study was traced in the preliminary report and will not be repeated here.

METHOD

All patients treated by both methods were subjected to detailed clinical and laboratory studies before treatment was instituted. All were studied by one of us. The treatment of all patients in both the malaria and the artificial fever series was administered in this clinic under our direct observation and supervision. Follow-up studies were made at six month intervals in the outpatient department of the Colorado Psychopathic Hospital except when the patients were incarcerated in the Colorado State Hospital. In such cases the follow-up studies were made by a physician from the Colorado Psychopathic Hospital. The majority of the postfever chemotherapy was administered in the outpatient department of the Colorado Psychopathic Hospital, although a few patients received their treatment from private physicians according to our therapeutic plan. Because of the cooperation of these private physicians and the staff of the Colorado State Hospital there is little difference in the type of follow-up care of these patients treated outside the Colorado Psychopathic Hospital Clinic. Social data, appointments for follow-up examinations and general aid in keeping track of the patients were handled efficiently by a trained psychiatric social worker who has this study as her principal duty. All follow-up examinations were made by a trained psychiatrist on duty in this hospital or in the Colorado State Hospital. The physicians making these follow-up studies were not aware of which type of fever therapy the patient had originally received. The patients in the malaria series in most instances received fifty hours of fever at 104 F. or more, although at times the patient's condition would not allow this amount of fever to be given. In the first three years of the study patients in the artificial fever series received fifty hours of fever at rectal temperatures of 105 F. to 106 F., given as ten treatments of five hours each. During the last two years of the study the artificial fever group received only thirty-six hours of fever but at a rectal tempera-

ture of 105.8 F. given as twelve treatments of three hours each. We could notice no difference in the results obtained from the shorter, more frequent treatments, and it enabled us to treat a greater number of patients in the artificial fever department. After fever therapy by either method complete laboratory and clinical studies were again made. Patients responding favorably were

Follow-Up Treatment

A. First year:

- Six months of trypanamide, 3 Gm. weekly
- Physical, mental, neurologic and complete serologic check-up
- Four months of bismuth salicylate, 0.26 Gm. weekly
- Two months of neosphenamine, 0.6 Gm. weekly
- Repeat examinations outlined under (b)

B. Second year:

Repeat procedure outlined for first year

C. Third year:

Repeat procedure outlined for first year

All treatment is continuous. Eyscgrounds and visual fields must be checked frequently. Repeat series as often as necessary. Patients not improved after three years will probably not benefit from further treatment.

transferred to the outpatient department and reported weekly for follow-up treatment. A small percentage returned to their private physicians for follow-up care, but they were encouraged to return to the clinic each six months for reexamination. The social worker keeps a rotating roster, and each six months each patient's name appears automatically. She then makes contact with the patient and arranges for a reexamination in the clinic. Those patients transferred to the state hospital in Pueblo are checked in that institution. We have had the usual difficulty in following our patients in their travels about the country, but the assignment of a social service worker to the task of getting the patients in for examination has made our follow-up treatments and examinations more complete than was possible prior to the inauguration of this system. For example, we were able to follow all of our patients treated with malaria and reported in the preliminary study¹ and 66 per cent of the artificial fever series studied in the same group for the entire five years or until they died. The periodic reexaminations consist of complete physical, neurologic and mental check-ups and serologic examinations of the blood and spinal fluid. It is interesting to note that most of the patients lost sight of during the follow-up period were patients who responded favorably to treatment and after two or three years of follow-up care felt free of symptoms and refused to come back for further examination. Some of those lost sight of moved out of the state and could not be reached. Most of the patients doing poorly have been admitted to the state hospital or have continued to come to this clinic seeking aid for their trouble. The deaths are, as far as we know, all recorded in the data.

RESULTS

The statistical evaluation of the results of any clinical research study is difficult at best. In a disease such as neurosyphilis there are so many variables, such as the duration of the infection before treatment, the type and quantity of prefever chemotherapy, the age and the physical and social status of the patient, that any sta-

tistical presentation is open to criticism. A detailed statistical analysis of a large group of cases was made by the Cooperative Clinical Group.⁵ We supplied a number of the cases in that study, and both the fever and the malaria series of the first year were included in that survey. We do not feel competent to make a detailed statistical breakdown of our data. We wish to present our general results and to mention certain trends noted in individual cases.

That the series are fairly comparable is indicated by the fact that 32 per cent of the patients in the artificial fever series and 31 per cent of those in the therapeutic malaria series were persons with advanced or so-called group A dementia paralytica. The average age of the artificial fever group was 40 years, and the average of the malaria group was 42.6 years, and the duration of symptoms prior to treatment was twenty-two and four-fifths months in the fever group and seventeen and one-fifth months in the malaria group. The data concerning prefever chemotherapy included vague recollections of "shots" taken years before the development of dementia paralytica as well as accurate clinical records from other hospitals and clinics. The reliability of the data varied so greatly in both series that no attempt was made at any evaluation of the influence it may have had on the course of the disease.

It will be noted in table 1 that more patients were treated by artificial fever than by therapeutic malaria. This was not due to variation in the selection of cases, but we have included in the artificial fever group 37 patients rejected from the comparative study because of the presence of diabetes, healed tuberculosis, cerebral arteriosclerosis, chronic nephritis and mild cardiac decompensation. Patients suffering from these disorders are not suitable for malaria therapy but may be given artificial fever with caution. In some instances the rectal temperature of the artificial fever was lowered to 104 F. It was felt, however, after a study of these cases that they should be lumped with the other cases suitable for either form of treatment in that these disorders probably do not greatly influence the course of the neurosyphilis other than by contraindicating malaria therapy. The results in this small group did not significantly alter the general picture.

TABLE 1.—Types of Treatment and Clinical Results

Clinical Status	Artificial Fever		Therapeutic Malaria	
	No. of Cases	Per-centage	No. of Cases	Per-centage
Remission.....	25	19	7	7
Improved.....	68	50	50	51
Unimproved.....	31	22	27	27
Died within three months of treatment.....	2	1.4	5	5
Died subsequently.....	8	6.6	9	9
Total.....	134	99	93	99

The general results of the study are included in table 1. Remission or improvement was noted in 69 per cent of the artificial fever group as compared with 58 per cent in the therapeutic malaria group. By remission is meant the condition of patients who are showing no clinical symptoms of their disorder and who have been able to resume their previous role in the community. Improved patients are those who are definitely better than when treatment was instituted but are operating at a lowered level of efficiency. The inter-

esting fact is that there was approximately the same difference between the two series in the preliminary or first year of this study. In other words, the rate of improvement during follow-up care and the rate of relapse are approximately the same in the two series, and the difference in our hands seems to be a difference in immediate results.

TABLE 2.—Group Classification in Relation to Clinical Results

Clinical Status	Artificial Fever						Therapeutic Malaria					
	Group A		Group B		Group C		Group A		Group B		Group C	
	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%
Remission.....	0	0	16	23	9	45	0	0	4	7	3	25
Improved.....	18	41	39	54	11	55	9	29	35	64	6	50
Unimproved.....	19	43	12	17	0	0	15	48	11	20	1	8
Died.....	7	16	3	4	0	0	7	23	5	9	2	17
Total.....	44	100	70	98	20	100	31	100	55	100	12	100

We cannot be certain as to the reasons for this difference, but some of the factors which may play a role will be mentioned. The most important difference in the two series may be the fact that with artificial fever therapy the patients may be safely treated at higher levels of temperature than is possible with therapeutic malaria. The importance of high levels of temperature has been shown by the Cooperative Clinical Group study.⁵ Another factor which may play a role is that patients usually gain weight during artificial fever therapy and in most instances are in better physical condition at the conclusion of the febrile period than when it was first instituted. The patients with malaria, on the other hand, usually lose weight and have some degree of anemia in spite of energetic attempts to prevent it. We originally felt that the difference was largely due to the fact that we administered trypanamide with each artificial fever treatment. In order to check on this for the last two years of this study we did not give trypanamide during the period of fever. In place of this, half of the patients with artificial fever received 0.3 Gm. of neoarsphenamine and 0.26 Gm. of bismuth salicylate during every other heating and the other half of the patients treated with artificial fever during the same period received no chemotherapy. We could see no significant difference between the two groups, nor could we see any significant difference between them and the larger group receiving trypanamide with their heating. Therefore we believe that the first two factors are the important ones, although the added chemotherapy must be of some benefit even though it failed to be statistically significant in this relatively small series.

Table 2 presents the clinical results according to the severity of the infection. Group A is advanced or severe dementia paralytica, group B the intermediate and group C the mild form. Detailed definitions of this grouping are contained in the original article.¹ The results are good with both methods in the mild cases and treatment becomes progressively less effective as the severity of the process increases. We obtained no true remissions in the advanced or A group by any form of treatment, but in many instances we were able to bring about definite improvements by either method of nonspecific treatment. The report of the Cooperative Clinical Group⁵ showed artificial fever to be ten times as effective as therapeutic malaria in advanced dementia paralytica. Our study also shows a superiority of the artificial fever method in this group (table 2) but a superiority of only 12 per cent.

Our experience parallels that of Solomon⁶ and others that intensive follow-up chemotherapy is essential if optimum sustained results are to be obtained. The variation in results reported from various clinics might be explained on the basis of care in follow-up treatment and examinations. The fact that the results in our series are superior to those reported in some clinics and inferior to others may well be due to this fact. We have found that in recent years the employment of a social worker and a greater drive to keep patients coming in for treatment and check-ups have certainly increased the beneficial results obtained in the patients given malaria therapy as compared to those patients treated with malaria before this study was inaugurated. For example, in the years 1925 to 1931 we treated 219 patients with dementia paralytica with therapeutic malaria. Of this group 45.6 per cent showed a remission or improvement. Our present malaria series reveals that 58 per cent of the patients are in some manner improved by the treatment, which means an improvement of 12.4 per cent in results from therapeutic malaria in the present study. We believe that this difference is due largely to greater care during the course of the malaria and greater emphasis on follow-up chemotherapy and supervision. Both of these groups were treated with therapeutic malaria in this hospital and, incidentally, with the same strain of tertian malaria.

The serologic response appears to show a greater modification in the group treated with artificial fever (table 3). The difference in results is not great and roughly parallels the difference in the rate of clinical remission. While we noted no direct correlation between alteration in serologic conditions and clinical remission in individual cases, we do find a higher percentage of serologic reversals in the group in both series showing great improvement than in those showing less improvement or no change in clinical status. Reversal or even great alterations in the serologic state immediately after the course of fever or malaria were rare but when they did occur seemed to indicate a good clinical prognosis. In several cases, on the other hand, great clinical improvement has been maintained in persons with spinal fluid persistently positive for syphilis. In our small series a decrease in the cell count and protein of the spinal fluid to within normal limits immediately

TABLE 3.—Serologic Results in Cerebrospinal Fluid

Clinical Status	Artificial Fever		Therapeutic Malaria	
	Number of Cases	Percentage	Number of Cases	Percentage
Reversed.....	15	11	6	6.1
Improved.....	47	35	28	23.5
Unmodified.....	47	35	40	40.8
Unable to check.....	25	18	24	21.4
Total.....	134	99	98	99.8

after treatment with artificial or malarial fever usually indicated that a considerable alteration or reversal of the Wassermann reaction and the colloidal gold curve was to be expected in six to twelve months provided the patient continued on the program of postfever chemotherapy. The changes in the status of the blood serum are inconstant and of practically no value in evaluating either the clinical course or the status of the spinal fluid.

6. Solomon, H. C., and Epstein, S. H.: Dementia Paralytica: Results of Treatment with Malaria in Association with Other Forms of Therapy, *Arch. Neurol. & Psychiat.* 33: 1008-1021 (May) 1935.

CONCLUSIONS

In a five year study 232 patients with dementia paralytica have been treated with either therapeutic malaria or artificial fever therapy. The follow-up therapy in the two groups has been as nearly identical as the vagaries of clinical practice will allow. The method of therapy with artificial fever has been safer and has been productive of better results. The importance of follow-up care is emphasized. Improvement in the care of patients during malaria therapy and more attention to follow-up medication has improved the results of malaria therapy in our clinic, although these results still remain inferior to the results obtained with artificial fever therapy.

Patients with physical contraindications to therapeutic malaria may, in many instances, be safely treated with artificial fever therapy. Either method is reasonably efficient if properly managed and if general follow-up treatment and care are adequate.

The serologic responses roughly parallel the clinical results in the two series. Careful, periodic, clinical reexamination offers the best guide for therapy and gives the most reliable data for evaluation of results.

CALCIUM DEPOSITS IN THE SHOULDER
AND SUBACROMIAL BURSITIS

A SURVEY OF 12,122 SHOULDERS

BOARDMAN MARSH BOSWORTH, M.D.

NEW YORK

The title of this paper is purposely indefinite. It is intended to cover calcium deposits observed in the tendons of the four short rotator muscles of the shoulder and the inflammatory condition of the overlying serous bursa to which these deposits not infrequently give rise. That others have experienced difficulty in devising an appropriate label for this pathologic entity is well attested by the diversity of captions used by many who have written on the subject in the last two or three decades. It has been described as "periarticular calcifications,"¹ "para-articular calcifications,"² "subacromial" or "subdeltoid calcifications,"³ "humeroscapular" or "scapulohumeral peri-arthritis,"⁴ "para-arthritis,"⁵ "Duplay's disease,"⁶ "calcified bursitis,"⁷ "calcic bursitis,"⁸ "calcification of

the subacromial bursa,"⁹ "rheumatism" or "neuritis"¹⁰ and "painful shoulder."¹¹

The fact remains that calcium deposits in the tendinous cuff which forms the capsule of the shoulder joint have for some time been recognized as a potential source of shoulder pain. The anatomy of this region, the pathologic changes encountered, the composition of the calcium deposits and their relation to the subacromial bursa are now quite well known, chiefly as the result of Codman's work on the shoulder;¹² yet little precise information is available as to the incidence of such deposits in the general population, what factors cause or contribute to their formation and what plan of treatment offers the best prospects of relief and cure of those deposits which give rise to symptoms.

Through observation of a large group of presumably normal persons over a period of years, much interesting and pertinent material on these points has been accumulated.

During the three year period from 1937 through 1939, 6,061 unselected persons were subjected to physical and fluoroscopic examination of both shoulders in connection with a routine examination at the home office of the Metropolitan Life Insurance Company; 5,061 were company employees while 1,000 were applicants for insurance or for employment. Of the whole group 165 (2.7 per cent) were found to have calcium in sufficient amount to show on fluoroscopy in one or both shoulders. The incidence of calcium formation was exactly the same in the employee and the nonemployee groups.

An analysis of both groups on the basis of sex, age and occupation has been made. Since, however, it has been possible to study the 5,061 employees much more intensively and to follow them with reexamination at annual intervals, the remainder of this report will be confined to them unless expressly stated otherwise.

Before employment each applicant is subjected to a thorough physical and laboratory examination, including roentgenograms of the chest. Throughout the period of employment a detailed medical record is kept of serious and minor ailments as well as of annual physical and fluoroscopic examinations of the heart and lungs.

The 5,061 employees were taken in succession as they came for the annual health examination. They include 3,883 females and 1,178 males, of whom 89.4 per cent were under the age of 40. Seventy and nine-tenths per cent did purely or mostly clerical work, 23.2 per cent used either a typewriter or similar manually operated machine exclusively, while the remainder were employed in miscellaneous occupations such as messengers, elevator operators, porters and cleaners.

It is obvious that the group studied constitutes a selected portion of the general population as to physical condition (preemployment and annual examinations), sex (76.7 per cent females), age (89.4 per cent under 40) and occupation (94.1 per cent clerks or typists).

Dr. H. H. Fellows, assistant medical director of the Metropolitan Life Insurance Company, and Drs. R. K. Felter, J. H. Inkster, Eleanor Murphy, Mary E. O'Sullivan and Peter Sabatelle assisted in this study.

It is in the main a cross section of the so-called white collar class of workers.

In the course of routine annual fluoroscopic examination of these 5,061 employees, visible calcium deposits were found in one or both shoulders of 138 (2.7 per cent).

TECHNIC OF EXAMINATION

Since this investigation was based on a search of several thousand supposedly normal shoulders for possible calcium deposits, it is apparent that roentgenography of each shoulder was not only highly unpractical but essentially valueless. Not only would many films have to be taken of each shoulder in different planes but this would have to be repeated each time the person was subsequently examined, and even then some calcium collections would be overlooked.

Good sized deposits may easily be missed unless they are seen in profile. It is quite usual for the calcium to be spread out in a thin layer, which is effectively obscured by the humeral head until the arm is rotated

the formation of calcium deposits. Only percentages based on an adequate number of persons examined in each group are of significance in a comparative study.

Sex.—Although the majority of persons with calcium deposit were females, deposits were found with greater relative frequency in males (3.6 per cent) than females (2.5 per cent) in the whole employee group.

Age.—Again, despite the fact that 70.3 per cent of all positive results were found in persons under 40, the incidence of calcium deposits in both males and females rose with the advance of years, by decades, up to the age of 50, after which it declined sharply.

Blood Calcium.—Blood calcium values were determined for 20 persons of this series, all with large deposits in one or both shoulders. Some were suffering from an acute bursitis; others were not. In every instance normal values were obtained.

Infection.—No one has succeeded in linking calcium deposition in these tendons or the associated bursitis to

so that the roentgen rays have to traverse not the thickness but the width or length of the deposit (fig. 1). For these reasons fluoroscopy is preferable to roentgenography in detecting the presence of calcium deposits and should never be omitted as a preliminary procedure. Similarly, no deposit should be considered completely absorbed unless the shoulder has been checked by fluoroscopy (fig. 3). Both shoulders should be examined in every case.

My practice has been to examine the shoulder with the fluoroscope throughout its full range of motion and take a spot-film of each deposit as it appears in profile, using a specially devised cassette holder which is hung on the fluoroscopic screen. The details of shoulder examination by a combination of fluoroscopy and spot-film roentgenography are beyond the scope of this paper and will be discussed elsewhere.^{12a} Excellent technical descriptions of roentgenography of the shoulder are available in the recent literature.¹³

ETIOLOGIC FACTORS

Care must be exercised in drawing conclusions as to the effect of sex, age, occupation and other factors on

a local infectious process (cultures taken at operation have always been negative; operative wounds do not suppurate) or to a past or present systemic infection. The opinion has been expressed that infection plays no part in the formation of calcium;¹⁴ the present investigation confirms this theory.

A careful search of the detailed medical records of all 138 persons showing calcium deposits was made for serious illness, arthritis, rheumatism and foci of infection, but none of these factors appeared to influence the formation or course of these deposits in the slightest degree. One hundred and seven (72 per cent) of the 138 employees with deposits were in the company's employ and subject to close, continuous medical observation for a period of ten years or longer, many of them for more than thirty years; yet of these only 23 had suffered any serious illness, and only 9 had a record of arthritis or rheumatism in any form. Fifty had some focus or foci of infection serious enough to require medical attention, usually of minor degree, at some time during their employment; more than half were tonsils and most of the remainder were sinuses.

Occupation.—Since there were very few male typists in this series of cases, a study of the effect of occupation on calcium deposit formation must be confined to females. A glance at the table will show that women typists had a significantly higher incidence of deposits than women clerks throughout all age groups up to the

age of 50. This seems to provide a positive answer to the question raised by Codman¹² as to the effect of occupation on the formation of deposits, and it substantiates his impression that "Millions of years of heridity have not prepared the modern stenographer or machine operator to keep their supraspinatus tendons stretched and under tension, on the qui vive hour after hour, day after day."

Therefore, while it cannot be proved that any particular job was responsible for a certain calcium deposit, nevertheless occupation as a causative factor must be given due consideration in deciding whether the work in question produced or helped to produce the deposit, when that work involves constant abduction of the arms for months and years.

Trauma.—The relation, if any, of trauma to calcium deposits and acute bursitis is one of the most interesting and at the same time most difficult problems presented by this symptom complex. "As these little calcified deposits now cause loss to the insurance companies, they are assuming more importance than when they only bothered the individual patient."¹² Any claim for compensation in this connection immediately raises the questions: Did the alleged trauma produce the lesion or aggravate an existing lesion, or was it merely coincidental?

Of 41¹⁵ shoulders with an acute attack of bursitis in only 7 was there a clearcut history of antecedent trauma which could reasonably be considered as precipitating the acute attack, and most of these traumas were of trivial nature. They are so typical as to be worthy of verbatim report: "while moving bureau to attic," "slipped on stairs and fell," "while gardening on return from vacation," "while scrubbing floor," "while reaching up to fix windshield wiper," "after a fall," "while putting on my coat."

In the remaining 34 acute attacks of bursitis the patient was unaware of any specific trauma or exertion as responsible for the condition. Several patients were

known calcium deposits in one or both shoulders with little or no symptoms for months or years prior to the acute attack.

In this series of cases, therefore, there is no statistical evidence that any single trauma per se was responsible for calcium deposition or for the acute attack of bursitis associated therewith. Trauma, when it did occur, has

Fig. 2.—M. F., a man aged 57, a clerk, had distention of bursa, greatly increased by treatment with heat. He had had slight symptoms diagnosed "myositis" (no roentgenograms were made) for three years, unrelieved by baking. There was sudden onset of acute bursitis (A). Symptoms were aggravated by three weeks of baking (B). Ultimate complete relief occurred with disappearance of calcium in one year (C).

seemed to be coincidental¹⁶ or at most the straw that broke the camel's back by merely precipitating an inevitable bursitis.

LOCATION AND SIZE OF DEPOSITS

Forty-six and four-tenths per cent of the 138 patients with calcium had bilateral deposits, calcium being visible in a total of 202 shoulders. Among those with unilateral deposits, the right shoulder was involved twice as often as the left.

As the tendons of the short rotators, the supraspinatus, infraspinatus, teres minor and subscapularis, are indistinguishably fused to form the capsule of the shoulder joint, it is at first difficult to determine which tendon contains the deposit. Practically, it makes little difference; the important thing is to locate the deposit in profile and note the rotation of the arm which brings it there. With practice and the use of a suitable spot-film roentgen technic, it is possible to attain a fairly high degree of accuracy in this procedure.^{12a}

Fifty-one and five-tenths per cent of the involved shoulders had calcium in the supraspinatus portion of the cuff, 44.5 per cent in the infraspinatus and 23.3 per cent in the teres minor. Only 5 shoulders showed calcium in the subscapularis. Calcium was visible in the subacromial bursa in 25 shoulders (figs. 2 and 3). This may seem surprising in view of the fact that there were 41 shoulders with an acute attack of bursitis, yet it confirms a rather common operative finding of milky, calcium-containing fluid in a bursa in an acute state which did not show on roentgen examination.

Variations in roentgen technic, in the contour of the person examined and in the shape of the deposit make classification of calcium formations according to size extremely difficult, yet a grouping of deposits from this standpoint is of considerable value in treatment and prognosis. For the purpose of this report, the following basis of comparison was used:

- Large: Deposits 1.5 cm. or longer in their greatest profile dimension.
- Medium: All others except:
- Tiny: Those barely perceptible on fluoroscopic examination.

According to this classification, 16.3 per cent of the shoulders showing deposits contained one or more large deposits, 54.5 per cent had medium ones and 50 per

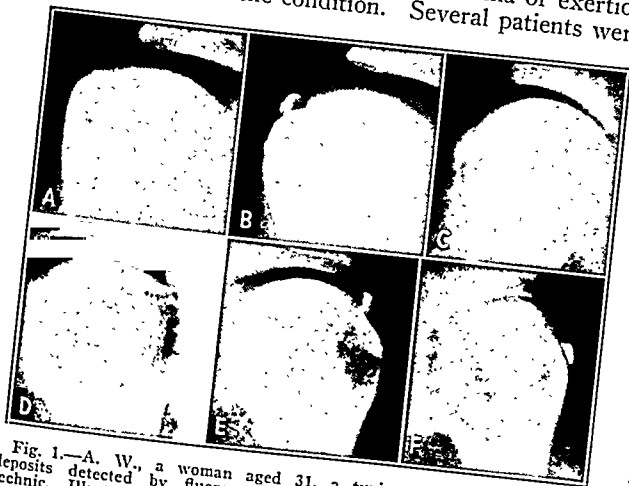

Fig. 1.—A. W., a woman aged 31, a typist, had multiple calcium deposits detected by fluoroscopy and roentgenography by spot-film technic. Illustrates the importance of fluoroscopic examination, with arm rotation, to bring out deposits hidden by the humeral head. She had had slight symptoms in both shoulders for four years, diagnosed "myositis" (no roentgenograms). A, B, C: Right shoulder: external, mid and internal rotation. D, E, F: Left shoulder: external, mid and internal rotation.

merely awakened suddenly during the night, without warning, by acute pain in the shoulder. It should be noted, furthermore, that many of these patients had had

15. Eighteen of these occurred among the 138 employees in whom deposits were found on routine fluoroscopy; 23 occurred among 29 additional employees who were seen initially for relief of their symptoms.

16. Carnett, J. B., and Case, E. A.: Clinical and Pathological Discussion of So-Called Subacromial Bursitis, S. Clin. North America 9: 1107-1126 (Oct.) 1929. Codman.¹²

cent had tiny accumulations. Multiple deposits occurred in 20.3 per cent of the involved shoulders. In a number of cases the joint capsule was studded with bits of calcium as though with buckshot (fig. 1).

APPEARANCE AND DISAPPEARANCE OF CALCIUM

The slowly progressive accumulation of calcium and its regression are clearly depicted in a series of roentgenograms taken of one patient during the past eight years. A woman aged 29, a machine operator, had had painful deposits in both shoulders since 1932 (fig. 3). An acute attack of bursitis of the right shoulder in 1934 was partially relieved by baking and diathermy, with regression but not complete disappearance of the deposit. Meanwhile the calcium collection in the left shoulder has grown steadily larger, with progressively increasing symptoms. She manages to perform her work and thus far has consistently refused treatment of the left shoulder, although she has repeatedly been advised to have the calcium removed. In view of the past history of this shoulder it will be of particular interest to observe whether the onset of the acute attack

sized or tiny. Every large deposit gave rise to symptoms before disappearing completely.

SYMPTOMS

Seventy (34.6 per cent) of the 202 involved shoulders caused some degree of pain or discomfort at one time or another, either prior to or during the period of observation. This varied from an occasional "twinge" or "hitch" in dressing or in doing the hair to complete disability, with intense pain and muscular spasm. Nocturnal discomfort was most frequently mentioned, consisting of great difficulty in finding a comfortable position in bed at night. Probably this is due in some measure to release of traction which the weight of the arm maintains with the patient upright during the day; with the traction removed, muscle tonus and spasm cause increased pressure on the painful deposit. In addition, of course, it is hard to sleep on one side all night, and there is nothing to divert the patient's attention from the affliction.

The majority of persons affected, on adequate questioning, were able to recall having had "trouble" with the shoulder previously. However, it is surprising how often even severe pain may be forgotten, for complaints were found in the past medical records of 5 persons who stated that they had never suffered.

Twenty-two (10.9 per cent) of the 202 involved shoulders gave rise to symptoms for the first time subsequent to discovery of the calcium on fluoroscopic examination; in 7 of these calcium deposits were observed to have remained without symptoms for from one to two years.

In 5 shoulders symptoms which called attention to visible deposits first developed subsequent to a negative fluoroscopic examination; 2 at two months, 1 at four months, 1 at six months and 1 at about one year after the negative examination.

In order to estimate the severity of symptoms, the 70 painful shoulders have been divided into three groups: acute, mild and slight. Symptoms are notoriously difficult to evaluate. Some persons bear pain well and others do not. However, there is no mistaking an acute attack of bursitis; these are the really "acute." Other shoulders with less pain but sufficient to require treatment are classed as "mild" and those which cause some annoyance but no real pain form the "slight" group.

On this basis, the symptoms in 18 shoulders were acute, in 22 mild and in 30 slight. The size of the deposit in general accorded with the symptoms complained of, yet it is interesting to note that one third of the large deposits gave rise to no complaints whatever while under observation (fig. 4).

TREATMENT

The question of what form of treatment offers the best prospects of relief or cure of painful shoulder deposits is a difficult one. This affliction is sometimes self limited and self curative. It is common knowledge that an occasional case may become temporarily improved or even to all intents and purposes cured without treatment. I have seen this happen in 4 shoulders which went untreated and had complete

Fig. 3.—F. D., a woman aged 29, a machine operator, had calcium deposits with symptoms in both shoulders for eight years (referred to in text). Right Shoulder: A (1932), two medium size deposits; B (1934), acute bursitis; C (1938), calcium apparently all gone (roentgenograms without fluoroscopic examination); D (1939), calcium residue persists (fluoroscopic examination, with rotation, and spot-film roentgenograms). Left Shoulder: Progressive increase in deposit and symptoms: E, 1932; F, 1935; G, 1938; H, 1939.

of bursitis, which I believe is inevitable, coincides with any trauma.

Calcium appeared subsequent to a negative fluoroscopic examination in 29 (14.4 per cent) of the 202 shoulders showing deposits. All these deposits were seen within one year of the first (negative) fluoroscopic examination, 3 of them being discovered within as short a period as two months. It is conceivable that 1 or 2 of these may have been overlooked at the first examination, before our fluoroscopy technic had been fully developed; certainly the majority were not. Two were large deposits and half the rest were of medium size, easily seen.

Though calcium has often been observed to regress under treatment, and for that matter without treatment, in only 13 shoulders did it entirely disappear within the period of this study. Nine of the 13 presented symptoms. Of these, in 2 there was no treatment of any kind given, in 2 others the deposit was removed by operation and in 5 the deposit disappeared coincidentally with baking or diathermy. In the remaining 4 shoulders in which the calcium disappeared under observation there were never any symptoms nor was any treatment given; all these deposits were medium

spontaneous remission of symptoms. This fact, of course, makes it possible for the proponent of any particular form of treatment to claim cures for his own method. Thus an element of confusion and uncertainty is added to the problem, and one is wise to keep this in mind when analyzing any series of end results.

The present report is no exception. It is admitted that a certain (unknown) number of those patients listed as cured by any one of the modes of treatment which were used might have obtained full relief without treatment. However, as this factor of uncertainty applies equally to all the therapeutic methods under consideration, a comparison of the end results of those methods is still significant.

During the three year period of investigation there were seen 40 shoulders of patients not included in this study in which relief from painful deposits was sought. In estimating results of treatment, these 40 shoulders have been added to the 70 painful shoulders in which the deposits were first found on routine fluoroscopic examination, making a total of 110 painful shoulders which came under observation. Among these 110 shoulders were 33 in which treatment was refused. The other 77 received baking, diathermy, excision or irrigation of deposits, singly or in combination, with ultimate complete relief in half and partial amelioration of symptoms in most of the rest.

A mere statistical summary such as this does not, however, tell the whole story. Many of those patients counted as fully relieved by baking or diathermy or both were under treatment, with pain and disability, off and on for years. As many as sixty to eighty diathermy treatments were given to a single shoulder over a period of six to eight months in at least 2 instances, with little or no relief. Apart from the physical suffering incurred, the expense of treatment and the number of work days lost are factors of considerable importance to these patients and to insurance companies, when the latter are involved.

Frequently an acute attack was precipitated or a somewhat painful shoulder made worse by the application of heat (fig. 2). On the other hand there are occasional patients who have been completely relieved by a few baking or diathermy treatments; these I believe are ones which would have had spontaneous remission of symptoms regardless of treatment. In most cases there has been temporary or partial relief following conservative measures, with subsequent recurrent attacks in the same shoulder.

Although no conclusion as to the relative merits of these different modes of treatment can as yet be supported by statistics, owing to the small number of treated shoulders available, I have acquired certain convictions regarding treatment as a result both of this study and of experience in practice.

I agree with those¹⁷ who feel that the best treatment for the acute attack is prompt excision of the deposit.

In experienced hands it is a relatively minor procedure, done under local or general anesthesia through a small incision. It gives immediate, certain and complete relief which so far as I know has been permanent. The patients have had an average hospital stay of four days and have been able to resume their usual duties, with unrestricted shoulder motion, in three weeks.

I recognize the fact that irrigation¹⁸ will give relief in selected cases of acute involvement in which the bursa is well distended and free of adhesions, but it too is an operative procedure (less certain than excision of the deposit), to be done under anesthesia in a hospital, and I am not convinced that all the calcium, from tendon as well as from bursa, can be removed in this way in every case.

The application of heat by one modality or another¹⁹ is therapeutically sound, but as an adjuvant rather than as a primary or basic form of treatment. I use it following operation to speed healing and recovery.

Not one of the painful shoulders in this series was subjected to roentgen therapy.²⁰

Fig. 4.—Some large calcium deposits, thus far without symptoms, found on routine fluoroscopic examination: A, R. M., ♀, 35, typist. B, V. S., ♀, cleaner. C, K. D., ♀, 45, clerk. D, I. R., ♀, 46, clerk. E, P. T., ♂, machine operator. F, E. B., ♀, 42 clerk. G, H. T., ♀, typist. H, R. K., ♂, 40, clerk. Since this was written patient P. T. had a sudden acute attack of bursitis of the same shoulder and was operated on, with immediate complete relief.

Immobilization of the shoulder, whether by swathe or by plaster encasement, is mentioned only to be condemned, because of the real danger of the formation of adhesions.

My practice has been to explain to each patient as simply as possible the underlying anatomy and pathologic condition and what my experience has been with the various modes of treatment. Choice of therapy is then left largely to the patient. The result has been that only a few patients ask for immediate operative relief. The majority decide to try heat applications, baking, diathermy or short wave. Some obtain complete relief after more or less prolonged treatment, but in most cases the relief is temporary or partial, with

recurring attacks over a period of years. Six patients have returned for excision of the deposit.

While I feel that large deposits should be excised regardless of symptoms, to forestall the development of an acute attack of bursitis, no patient has yet been willing to have this done. Medium and tiny deposits should, in general, be treated conservatively and should be watched.

SUMMARY AND CONCLUSIONS

Among 6,061 supposedly normal persons of the white collar class, calcium was found on routine fluoroscopic examination in one or both shoulders of 165 (2.7 per cent). Of this series 5,061 were studied at annual intervals over a three year period and provide the material from which the following conclusions are drawn:

1. Fluoroscopy and spot-film roentgenography are invaluable aids in the detection and precise localization of calcium deposits in the shoulder.

2. Calcium deposits occur most commonly during the period of greatest activity of adult life, and especially among males.

3. Serious illness, arthritis, rheumatism and infection, whether local or systemic, past or present, exert no influence on the formation or regression of deposits.

4. Occupations that require constant prolonged abduction of the arms foster the formation of calcium deposits in the shoulder.

5. A single trauma per se does not cause calcium deposition, although it is occasionally associated with the onset of an inevitable bursitis.

6. Although fluoroscopically visible calcium deposits may form within as short a period as two months, most deposits require a considerably longer time for their formation.

7. Medium and tiny deposits may disappear without symptoms, but large deposits always result in a painful shoulder sooner or later, though they may remain quiescent and symptomless for months or years.

8. Excision of the deposit is recommended as the best treatment for the acute attack, since it offers immediate, certain, complete and permanent relief.

1045 Park Avenue.

A Liberal Profession.—Medicine today is probably the most liberal of all the professions of society. It recognizes addition to its knowledge from any source, and the present edifice of scientific medicine has been reared on the labor and contributions of innumerable physicians, scientists and lay people, regardless of race, color or creed. Medicine is the most international of sciences and therefore least nationalistic. It comprises a democracy of intelligence, knowing neither geographic nor racial bounds. Medicine has no bench or bar; the lawyer must pay deference to the judge, who intellectually may be his inferior; neither has medicine a hierarchy as in the case of the ecclesiastical profession. In medicine all men are alike; there are no castes, no orders, no class distinctions. Its devotees meet on common ground in practice, in research, in hospitals, in schools and in conventions, where eager minds come together for mutual improvement and understanding. . . . Medical science has done much to make possible the state of society as it exists today.—Abell, Irvin: *The Spirit of Medicine, Pharos of Alpha Omega Alpha*, May 1941.

CENTRAL NERVOUS SYSTEM MANIFESTATIONS OF INFECTIOUS MONONUCLEOSIS

REPORT OF A CASE

RALPH LANDES, M.D.

JOSEPH P. REICH, M.D.

AND

SAMUEL PERLOW, M.D.

CHICAGO

Involvement of the central nervous system in infectious mononucleosis is rare, but probably not as rare as the dozen or so cases thus far reported would seem to indicate. What is more likely is that the nervous system involvement so masks the other manifestations of the disease that the diagnosis is overlooked.¹ The nervous symptoms may appear as much as two weeks before the characteristic lymphadenopathy and splenic enlargement² resulting, if the characteristic blood picture is overlooked, in the erroneous diagnosis of lymphocytic choriomeningitis, acute toxic encephalitis, epidemic encephalitis or early poliomyelitis.

The neurologic symptoms produced may be multiple. All patients have headaches. There is a varying degree of dulling of the sensorium from mild lethargy to coma. The patient may be irritable and irrational.¹ There may be photophobia, nystagmus and poor articulation.³ Peripheral neurologic symptoms, such as facial nerve palsy, oculomotor nerve involvement, optic neuritis and anosmia, are occasionally present. Signs of meningeal irritation are usually present with positive Kernig and Brudzinski signs, nausea and vomiting.

The spinal fluid has been examined in only a few cases, and the conditions found are neither characteristic nor constant. The pressure may or may not be moderately elevated. Pleocytosis is variable, usually from 25 to 300 cells, largely lymphocytes. On one occasion a cell count over 1,000 was reported.⁴ In our case the cell count at the height of the disease was normal. The total protein may be increased, as may the globulin fraction. The spinal fluid Wassermann reaction and colloidal gold curves are negative. Schmidt and Nyfeldt⁵ and Huber⁴ found abnormal spinal fluids in several cases of infectious mononucleosis in the absence of any nervous system symptoms or signs. Schmidt and Nyfeldt⁵ were also able to obtain cultures of *Listerella* from the spinal fluid in 4 of 5 cases. Cerebral symptoms were present in only 1 of these cases.

Characteristically the nervous system symptoms and signs disappear, with no residuum. The spinal fluid returns to normal some time after the symptoms and signs disappear.¹

REPORT OF CASE

B. S., a white man aged 21, was admitted to the Michael Reese Hospital on May 19, 1940 complaining of severe headache, dizziness, vomiting and a staggering gait of one week's duration.

From the Michael Reese Hospital.

1. Epstein, S. H., and Dameshek, William: Involvement of the Central Nervous System in a Case of Glandular Fever, *New England J. Med.* 205:1238, 1931.

2. Gsell, O.: Serous Meningitis in Pfeiffer's Glandular Fever (Infectious Mononucleosis), *Deutsche med. Wchnschr.* 63:1759, 1937.

3. Marshall, E. A.: Infectious Mononucleosis, *Am. J. Clin. Path.* 9:298, 1939.

4. Huber, W.: Serous Meningitis in Pfeiffer's Glandular Fever, *Schweiz. med. Wchnschr.* 68:892, 1938.

5. Schmidt, V., and Nyfeldt, A.: Regarding Infectious Mononucleosis and Meningoencephalitis, *Acta oto-laryng.* 26:680, 1938.

He was well until approximately ten days before admission, when he had severe pain in his calf muscles lasting one day. On the following day the pain subsided, but dizziness and headache began, which gradually became more severe, especially while he was in the erect position. His gait became very unsteady. Frequent attacks of nausea and vomiting followed. Five days before he entered the hospital these symptoms became so severe that he was obliged to stay in bed. The patient was very irritable at first but later became more and more lethargic, and at times responded irrationally. He complained bitterly of the headaches, which were retro-orbital and frontal. His temperature during the week prior to admission rose to 101 F. during the evening but fell to 99 in the morning. There was no history of a sore throat, cold or cough in the recent past. The past history and family history were noncontributory. He was employed in a fruit commission house where only California fruit was handled. There was no history of insect or animal bite or of head injury.

On physical examination the patient appeared well nourished and lay quietly in bed, exhibiting but little interest in his surroundings. The temperature was 100 F. and the pulse rate 100 per minute. The skin showed no petechiae, ecchymoses or eruptions. It was warm, and perspiration was profuse. The conjunctivas showed no petechiae or icterus. The extraocular muscles were normal. There was no nystagmus. The pupils reacted normally to light and in accommodation, were equal in size and were regular. The fundi were normal. The tongue was heavily coated and dry. There were several carious teeth. The mucous membrane of the pharynx was not injected. The tonsils were absent. There was no cervical adenopathy. The lungs and heart were normal. The abdomen was soft and not tender. No masses were palpable. The spleen, liver and kidneys were not palpable. There was no cyanosis or edema of the extremities or axillary, epitrochlear or inguinal lymphadenopathy.

Blood heterophile agglutination titer.

Neurologic examination revealed a freely movable head and no neck rigidity. The head was not tender on percussion. The eyes were normal. Likewise the other cranial nerves were intact. The speech was poorly articulated; the words were slurred, somewhat explosive in character and often hardly understandable. Reading aloud exaggerated these peculiarities. The ability to see the printed words did not seem impaired. Muscular movement, tone and strength were normal. However, the muscular coordination was very poor. In the finger-to-nose test the nose was missed consistently, and the movement was not smooth but was broken up into several stages. In the heel-to-knee test the heel was brought to the knee fairly accurately, but when the patient was directed to leave it there or to slide the heel downward along the tibial crest the foot shook violently, and there was extreme unsteadiness and deviation. Standing was possible only with the legs spread widely apart, and even then there was pronounced swaying. When the feet were brought together the patient tended to fall backward. Walking was extremely unsteady and almost impossible. Sensation was normal for touch, pinprick, movements and vibration. Reflexes were normal except for a more vigorous radial jerk, absent left cremasteric and absent cutaneous abdominal reflexes. The knee jerks and ankle jerks were normal. The Babinski reflex was absent.

The patient was slow in understanding and almost stuporous. Occasionally one had to speak to him loudly to maintain his attention. He attempted to cooperate but followed directions very poorly. His answers were very slow in forthcoming, but fairly reasonable. When the patient's extremities were placed in the most uncomfortable positions, he tended to maintain that position in almost catatonic manner. His face was devoid of expression.

The impression at this time was that we were dealing with an encephalomyelitis secondary to some unknown systemic infection. The patient's symptoms remained unchanged on May 20 and 21 but began to improve on the 22d and continued improving until his discharge. The high mononuclear count (50 per cent) present on the day following admission provoked comment, but it was not until the laboratory reported a blood heterophile

agglutination titer of 1:1,024 that its significance became clear. Reexamination of that blood film and all subsequent blood films demonstrated the typical blood picture of infectious mononucleosis (table 1). There was a high lymphocyte percentage. The lymphocytes showed much variation in size. The nuclei were darkly stained and contained many vacuoles. There was a shift to the left among the granulocytes, with many unsegmented cells. There were also many disintegrating and degenerate neutrophils. The frequently repeated blood studies (table 1) show the gradual decrease in monocytes and large lymphocytes as recovery progressed. A stool passed on the 20th was reported having 3 plus occult blood. For this reason bleeding, coagulation and prothrombin times were determined and found normal (1 minute 10 seconds, 3 minutes five seconds and 30 seconds respectively). The platelet count was 220,000 per cubic millimeter.

It is interesting that careful reexamination each day after the nature of the illness was recognized failed to reveal enlarged lymph nodes until May 31 (twelve days after the patient entered the hospital and twenty-two days after the onset of symptoms), when several large glands were found in the neck and a chain of large glands appeared in both inguinal regions. Later the axillary nodes became enlarged. On June 3, twenty-five days

after the onset of the illness, the spleen became palpable on deep inspiration.

Table 2 shows the spinal fluid findings. Fluid drawn the day following admission was found to have a normal cell content with a considerable increase in the total protein content and the globulin fraction. Fluid drawn on June 1, after almost all the neurologic abnormalities had disappeared, showed almost the same high protein level and a slightly elevated count. Fluid drawn on June 6, the day before the patient was discharged and after he had been symptom free for more than a week,

showed a greatly reduced but still elevated protein content. The Pandy and Ross-Jones tests were only slightly positive. The cell count was normal.

We have read no reports of spinal fluid examination for heterophile agglutinins in infectious mononucleosis. Serial dilutions beginning with 1:4 concentrations revealed no such agglutinins in our case. Blood and spinal fluid cultures remained sterile.

The chart shows the rapid fall in blood heterophile agglutinins during recovery to an almost insignificant degree just prior to the patient's discharge from the hospital.

Agglutination tests of the patient's serum against *Listerella monocytogenes* were negative. Throat cultures made on the day of admission showed only alpha streptococci. The urine was constantly normal.

COMMENT

This case is almost unique among the cases of infectious mononucleosis which showed involvement of the central nervous system, in that there were no signs and almost no cerebrospinal abnormalities (except for 9 cells in one count) pointing to meningeal involvement. Especially striking was the cell protein dissociation in favor of the protein, which speaks against involvement of the meninges. In the majority of the cases reported there was meningeal involvement with a considerable increase in cell content, at least during one phase of the disease, while the protein showed hardly any increase.

Only one case has been reported⁶ in which the symptoms (paresis of the left inferior rectus muscle of the eye, highly exaggerated knee jerks, a questionable plantar reflex and entirely normal cerebrospinal fluid) pointed to a purely encephalitic process.

In our case the cerebral involvement was much more extensive. The clinical picture was that of an acute ataxia with outspoken involvement of the cerebellar system.

This is not the place to discuss at any length the question of the localization of the acute ataxia, whether it is produced by the toxic-infectious process of the coordination system (Davidenkoff) or by a circumscribed focus in the hypothalamic region (Margulis). It seems, however, that the pathologic process, whether it is a real "encephalitis," i. e. an inflammatory process, or a "toxic encephalopathy," extends over a rather large area of the brain. In our opinion there cannot be any doubt about the involvement of the cerebellar system. On the other hand there were a number of signs (expressionless face, lack of motor impulse, peculiar kind of somnolence, diffuse perspiration) which make one think of a pathologic process in the gray matter surrounding the third ventricle, the hypothalamic region, so that the possibility of a lethargic encephalitis was considered for a short time.

It is interesting that the lymphadenopathy and palpable spleen, the usual and characteristic signs of infectious mononucleosis, did not appear until the alarming cerebral symptoms were almost gone. We must admit that the diagnosis would have probably been missed except for the laboratory report of positive blood heterophile agglutination, and the case would have been relegated to that wholly unsatisfactory waste-basket category of "aseptic" or "toxic encephalitis." We feel, therefore, that in the presence of acute cerebral symptoms of unknown etiology the heterophile agglutination test should be made.

Several workers have reported isolating *Listerella* in infectious mononucleosis. Schmidt and Nyfeldt were able to obtain cultures of the organism from the spinal

fluid in 4 of 5 cases of the disease, in only 1 of which were cerebral symptoms present. In our case three attempts at obtaining cultures of the organism were unsuccessful.

The spinal fluid in our case was negative for heterophile agglutinins.

SUMMARY

1. In a case of infectious mononucleosis the only early symptoms simulated those of encephalitis.

2. The heterophile agglutination determination is of value in cases in which acute cerebral symptoms of unknown etiology are present.

TREATMENT OF PARALYSIS AGITANS WITH VITAMIN B₆ (PYRIDOXINE HYDROCHLORIDE)

A. B. BAKER, M.D.

MINNEAPOLIS

Pyridoxine hydrochloride, or the vitamin B₆ fraction of the vitamin B complex, was first discovered by György¹ in 1935 and was first prepared synthetically in 1939 by Harris and Folkers.² It consists of 2-methyl-3 hydroxy-4, 5-dihydroxy-methyl-pyridine. It was first used clinically by Antopol and Schotland³ with beneficial results in 6 patients with pseudohypertrophic muscular dystrophy. These authors expressed the belief that the drug, through its pyridine structure, was involved in the enzyme system concerned in muscular metabolism. Jolliffe,⁴ believing muscular metabolism to be involved in paralysis agitans, tested the drug in this condition. He reported its use in 15 patients with paralysis agitans, all of whom had severe involvement. All patients received 50 to 100 mg. of pyridoxine hydrochloride intravenously. Four of the 15 patients showed definite objective improvement. The best results occurred in the idiopathic or arteriosclerotic type of the disease.

Since a considerable proportion of the patients visiting the Outpatient Clinic of the University of Minnesota Hospitals suffer from paralysis agitans, the staff naturally was most anxious to obtain and try any new therapeutic agent that might offer possible aid to these unfortunate persons. A group of 15 patients suffering from paralysis agitans were, therefore, selected for intravenous therapy with pyridoxine hydrochloride.

The type of patient, the amount of treatment and the results of the therapy are shown in the accompanying table. Nine obtained only two weeks of treatment at daily intervals; 6 of these received only 50 mg. of pyridoxine hydrochloride; 2 received 50 mg. for one week and 100 mg. during the second week, while 1 received 100 mg. for two weeks, supplemented by 54 grains (3.5 Gm.) of brewers' yeast. Three patients showed definite objective improvement (in cases 1, 10 and 12). Of these, 1 had idiopathic parkinsonism and 1 had postencephalitic involvement, while the condition

From the Division of Nervous and Mental Diseases, University of Minnesota Medical School.

The vitamin B₆ used in these studies was hexabion hydrochloride, furnished by Merck & Co., Inc.

of the third patient, although she offered no history of any previous illness, suggested postencephalitis, since the age at onset was 39.

Six patients received daily intravenous treatment with pyridoxine hydrochloride for three or more weeks. This treatment was supplemented with the whole vitamin B complex in the form of 54 grains daily of brewers' yeast. In 5 of these patients the illness was idiopathic, while in 1 it was postencephalitic. Three patients, all of whom had idiopathic parkinsonism, showed definite objective improvement. Neither the age of the patient nor the duration of symptoms seemed to have any effect on the treatment. Good results were obtained in persons whose illness had been present for as long as fifteen years, while often no improvement occurred in some whose illness was fairly recent. The most favorable results appeared in the idiopathic type of the disease. This is in agreement with the results reported by Jolliffe.⁴ The nature of the improvement varied from patient to patient. In some it consisted of a drastic reduction in the severity of the tremor; in others the tremor was only slightly affected while the rigidity improved, allowing the patient more freedom in movement. All the patients benefiting from the drug reported a definite subjective improvement, consisting of a decreased fatigability, better sleeping and increased appetite. One patient had gross choreiform movements rather than a parkinsonian syndrome. Since the involvement probably was arteriosclerotic and also extrapyramidal, it seemed of interest to attempt therapy with pyridoxine hydrochloride. Her improvement was most striking, suggesting the possibility that this type of therapy may be of benefit in other types of extrapyramidal involvement. A brief report of those patients responding to this therapy will aid in evaluating the results.

REPORT OF CASES

CASE 1.—E. C., a woman aged 67, first noticed a definite tremor and rigidity of her hands in 1935. The involvement gradually spread to almost all the muscles of her body, including the muscles of the trunk, producing at first a shuffling gait and mild postural changes and finally an almost complete invalidism, the patient ultimately being confined to a wheel chair. She became weak and for years was able to sit up only for short periods. She had difficulty in sitting up in a car during even a short ride. She had been treated with scopolamine hydrobromide but showed no response to this type of therapy.

Neurologic examination revealed a moderate tremor and extreme rigidity of all limbs. There was complete loss of facial expression and an absence of blinking. The patient was unable to walk or stand without aid. The deep reflexes were reduced but equal. The rest of the examination gave negative results.

She was given daily intravenous injections of 50 mg. of pyridoxine hydrochloride for one week and 100 mg. for the second week. Improvement became apparent after three weeks. Expression rapidly returned to the patient's face. Her tremor became reduced and at times would be completely absent, even under emotional excitement. The rigidity also diminished, so that the patient was soon able to sit up for long periods of time and was also able to walk about the house unassisted. Long rides and even the entertaining of company no longer fatigued the patient.

She has continued to maintain her improvement in spite of two severe gastrointestinal upsets.

CASE 6.—L. S., a man aged 47, a jeweler, in 1935 first became aware of an impairment in speech associated with a generalized bodily weakness. He described this weakness as a general slowing down of all his activities, primarily because of difficulty in using his muscles. Impairment in speech consisted in difficulty in getting words out and a general running together of his words as they came out. The muscular rigidity became more severe, retarding all his voluntary movements. Because

of this difficulty he soon became unable to carry on his work as a jeweler. His writing became impaired and his facies expressionless. Continuation of his illness finally resulted in the patient's complete inability to do any type of work.

The neurologic examination revealed a dysarthria and dysphonia associated with a masklike facies and a generalized muscular rigidity. Tremor was not present. Laboratory tests all gave negative results. The patient was placed on varying doses of scopolamine hydrobromide, which he continued to take for a period of months with no improvement. He was then given two courses of pyridoxine hydrochloride intravenously, separated by a two week interval. The first consisted of 50 mg. of the drug daily for a period of two weeks, the second of 50 mg. daily for one week followed by 100 mg. doses the second week. He was simultaneously given 54 grains of brewers' yeast daily. After the second week of his first course of treatment, the patient began to notice definite improvement in his speech. His voice lost part of its monotonous character and there was a definite ability to phonate better. After three weeks of treatment, his facial expressions became livelier. Improvement continued. The muscular rigidity became so reduced that the patient was able to play ball and perform much of the work which he had been forced to discontinue prior to his treatment. At present he is taking 20 mg. weekly of pyridoxine hydrochloride given orally and has maintained his striking improvement.

CASE 7.—A. G., a man aged 54, first noticed a slight stiffness in his left arm and leg in 1927. This rigidity gradually increased, producing a definite difficulty in gait. Three months after the onset of rigidity a coarse tremor appeared in the left hand and soon extended to the entire extremity but has always remained more or less localized to the left upper extremity. One year later there appeared an involvement of the facial muscles and a slight disturbance in speech. There was no history of any severe infectious process antedating the onset of his present illness.

Neurologic examination revealed a slight masking of the facies and a moderate sialorrhea. There was rigidity involving all extremities, being most noticeable on the left side, with a tremor limited to the left upper extremity. The patient had difficulty in performing both fine and gross movements with his hands. Scopolamine hydrobromide, which he had taken for a number of years, had produced but little improvement. During the past eight or nine years of his illness his condition had been more or less stationary.

He was given daily intravenous injections of pyridoxine hydrochloride, receiving a total of four weeks of treatment with 100 mg. of the medication. At the same time he was given 54 grains of brewers' yeast daily by mouth. After the completion of his treatment, the patient noticed a definite decrease in the tremor of his left upper extremity. His rigidity became reduced, and his impairment in speech completely disappeared. Whereas before the patient was able to walk for only short distances without becoming tired, he could now walk with ease for many blocks. He was given 40 mg. of pyridoxine hydrochloride by mouth weekly and in three months showed no recurrence of the involvement.

CASE 10.—C. S., a woman aged 54, first noticed a tightness of her legs in 1925. One year later there developed a mild tremor of her right hand associated with definite rigidity. This involvement remained localized to the lower limbs until 1938, at which time it spread rapidly to the other extremities. The progress of the illness had been rapid during the past few years, resulting in a slow and shuffling gait and a severe and annoying tremor in her arms. She had continued to walk and travel about unassisted, although she had refused to go out in company because of her condition. More recently a moderate sialorrhea and some scanning of her speech developed. The patient gave no history suggesting any previous involvement of the central nervous system, although her age at onset certainly was suggestive of a postencephalitic involvement.

Examination revealed the characteristic parkinsonian syndrome. The facies was expressionless, and blinking was infrequent. The impairment in speech was noticeable. There was considerable rigidity of all extremities, associated with a rapid,

shuffling gait. A severe tremor was present in the upper limbs and there were beginning contractures of the hands.

She was given a single course of daily intravenous injections of 50 mg. of pyridoxine hydrochloride the first week and 100 mg. the second week. Along with this medication she received 54 grains of brewers' yeast by mouth. After this

was a general slowing up of all her activities, and her gait became shuffling. She found it impossible to do her housework or to carry out her regular activities. At the time of her examination she presented a masklike facies, a staring gaze and a severe tremor and rigidity of all the extremities. She had a definite shuffling gait, walking with small steps and

Summary of Drug Therapy

Case No.	Patient	Age	Sex	Type of Paralysis Agitans	Duration of Disease, Years	Severity of Disease	Result of Treatment	Duration of Treatment, Weeks	Type of Medication	Daily Dosage
A. Pyridoxine Hydrochloride Given Intravenously										
1	E. C.	67	♀	Idiopathic	5	Severe	Definitely improved	2	Pyridoxine hydrochloride	50 mg. 1 week 100 mg. 1 week

15	L. B.	35	♀	Syphilitic	4	Severe	Unimproved	2	Pyridoxine hydrochloride Brewers' yeast	50 mg. 54 grains
B. Pyridine Hydrochloride Given Orally										
16	A. C.	69	♂	Idiopathic	3	Severe	Definite subjective improvement; mild objective improvement	3	Pyridoxine hydrochloride Brewers' yeast	50 mg. 54 grains
17	J. C.	60	♂	Idiopathic	2½	Moderate	Subjective improvement only	3	Pyridoxine hydrochloride	50 mg.
18	J. V.	62	♂	Idiopathic	10	Severe	Unimproved	3	Pyridoxine hydrochloride Brewers' yeast	50 mg. 54 grains
19	A. J.	69	♂	Idiopathic	3	Moderate	Unimproved	3	Pyridoxine hydrochloride Brewers' yeast	50 mg. 54 grains

course of treatment she was given 40 mg. of pyridoxine hydrochloride by mouth weekly.

Improvement began a few weeks after her treatment. The tremor immediately subsided almost to the vanishing point. Her rigidity improved so that she was able to get around much better. Her improvement has been maintained on the oral medication.

CASE 12.—G. F., a woman aged 39, first noticed her illness in 1936, at which time she suffered a mild tremor of the upper extremities. About six months after the onset of the tremor there appeared a definite rigidity of the upper extremities, a noticeable disturbance in speech and severe sialorrhea. There

finding difficulty in raising her extremities. She had been taking scopolamine hydrobromide, amphetamine sulfate and various other types of medication over a period of years, with little alleviation of her symptoms.

She was given daily intravenous injections of 50 mg. of pyridoxine hydrochloride, receiving treatment for two weeks. At the time of the completion of her treatment she showed no definite objective improvement. She was followed for a period of two months. Six weeks after the completion of treatment she began to improve. Her rigidity decreased to the extent that she was able to do her own housework and move about much better. The sialorrhea decreased remarkably, and her

tremor became almost imperceptible. She still has slight difficulty in speech, although this has also improved.

CASE 9.—I. M., a housewife aged 71, had been afflicted for the past twelve years with gross, bizarre, purposeless, involuntary movements which began first in the arms and later spread to the rest of her musculature. For the past three years this involvement had totally incapacitated the patient. Walking had been almost impossible, and she had been unable to care for or feed herself. The patient's mother had been similarly afflicted but not to the degree to which the patient was involved. The patient has one brother, aged 67, who has noted similar mild twitchings during the past few years. The other five siblings are unaffected. She has three daughters who are at present unaffected. The physical examination, aside from the normal evidences of senescence, revealed no abnormalities. The neurologic examination revealed continuous involuntary, irregular movements involving the upper portion of the patient's trunk, arms and head. These choreiform movements also involved, but to a much less extent, the lower extremities, so that walking was difficult and her gait slightly bizarre. Laboratory studies all gave negative results. Fluoroscopic examination of the chest and a 6 foot roentgenogram of the heart gave negative results. The diagnosis in this case was senile chorea.

The patient was given $\frac{1}{2}$ teaspoon (2 cc.) of a concentrated yeast (Anheuser-Busch) twice a day and pyridoxine hydrochloride intravenously daily in 50 mg. doses. The pyridoxine hydrochloride was increased to 100 mg. after the second week. These medications were discontinued after three weeks, and the patient was given 40 mg. of pyridoxine hydrochloride by mouth weekly. After the first few injections of the drug her condition showed improvement, which continued during the treatment. After three weeks the patient was walking unassisted and with ease, and her gait showed no observable abnormality. She was now able to write her own name. She could feed herself, but only with considerable difficulty. The choreiform movements were greatly reduced, and the patient could now sit quietly in a chair, whereas previously she had presented rather a bizarre picture. Subjectively the patient felt stronger. This manifested itself in an improved appetite and more restful sleeping.

COMMENT

Fifteen patients suffering from paralysis agitans were treated intravenously with pyridoxine hydrochloride, supplemented in most cases by the oral administration of brewers' yeast. The patients received 50 to 100 mg. of the intravenous medication at daily intervals for from two to four weeks. Nine patients had idiopathic or arteriosclerotic parkinsonism, and of these 4 were improved. One of these patients had senile chorea rather than true parkinsonism. This patient showed a most striking improvement, suggesting the possibility that therapy with pyridoxine hydrochloride may be of benefit in other types of extrapyramidal involvement. Of the remaining 6 patients, 2 showed improvement. In the latter group 3 had postencephalitic paralysis agitans and 1 the syphilitic form. In the remaining 2 patients the etiologic factors producing paralysis agitans were undetermined.

Four patients suffering from arteriosclerotic or idiopathic paralysis were treated orally with 50 mg. of pyridoxine hydrochloride daily for three weeks supplemented by 54 grains of brewers' yeast. Two of these patients insisted that improvement had occurred but in only 1 was there any objective benefit in the form of an observable decrease in the tremor and rigidity.

The small number of patients and the inadequate dosage do not allow any definite conclusions; however, the results with the oral medication are suggestive and have encouraged me to undertake further investigations with this method of administering pyridoxine hydrochloride, or vitamin B₆.

THE CEREBROSPINAL FLUID IN DELIRIUM TREMENS

MILTON ROSENBAUM, M.D.
CINCINNATI

Drainage of the cerebrospinal fluid by means of spinal puncture as a therapeutic measure in delirium tremens was introduced by Steinebach¹ in 1915. In that same year Hoppe² introduced this procedure in the United States; since then the treatment has become highly popular. Although it is now generally assumed that an increase in intracranial pressure occurs in delirium tremens and that drainage of the cerebrospinal fluid will relieve that tension, few data in support of this hypothesis can be found in the literature.

In a series of 18 cases, Steinebach found 14 patients (75 per cent) to have an increased pressure of the cerebrospinal fluid. However, this conclusion was based on his interpretation of any pressure above 150 mm. of water as abnormally increased, which criterion is not in accord with that generally employed in this country, in which the upper limit of normal is usually considered to be 180 mm. of water.³ All the pressures observed in his cases were not recorded by Steinebach and hence cannot be reevaluated. With no substantiating data, Hoppe also concluded that the pressure of the cerebrospinal fluid is "always increased in delirium tremens."² Similar conclusions without supporting data were made by Goldsmith⁴ from studies on patients with alcoholic deliriums and other acute alcoholic psychoses, in which he claimed that in 48 per cent of his cases the cerebrospinal fluid "came out under considerable pressure." Likewise, Levinson⁵ stated that in delirium tremens the "cerebrospinal fluid pressure is greatly increased, running as a rule from 150 to 300 mm. of water," but gave no data to support his conclusion. In a similar manner other authors,⁶ in discussing the treatment of delirium tremens, have expressed the belief that an increase in intracranial pressure occurs, even though ample demonstration of such a phenomenon is still lacking.

The only study on delirium tremens which cast some doubt on the aforementioned general conclusion was that of Thomas, Semrad and Schwab.⁷ These authors reported 40 cases of delirium tremens in 20 of which spinal puncture and drainage were done. In only 12 of their cases were readings of pressure reliable, but in all 12 the pressures of the cerebrospinal fluid were normal. In view of the small number of cases involved, these authors could not definitely negate the concept so generally accepted by others.

In view of the preceding reports, a review of the results obtained from examinations of the cerebrospinal fluid of patients with delirium tremens who were treated

in the Psychiatric Pavilion of the Cincinnati General Hospital during the past four years was considered to be of value.

The records of 234 patients with delirium tremens admitted to the Psychiatric Pavilion of the Cincinnati General Hospital during the past four years were reviewed for this study. In order to keep the problem unobscured, all cerebrospinal fluids which were contaminated by blood as a result of a traumatic tap or an injury to the head and all fluids which reacted positively to the Wassermann test were excluded from the series.

The punctures were performed in the lumbar region with the patient in the lateral recumbent position. Pressures were measured with the Fremont-Smith modification of the Ayer water manometer. All readings of pressure were discarded unless the patient was relaxed and the measured pressure was a reliable one. The cells were counted in a blood-counting chamber. The majority of the cell counts were made by the glacial acetic acid method, although in the last year Unna's polychrome methylene blue was used for staining the cells prior to counting. The protein determinations

10 cells per cubic millimeter in 7 (4 per cent) and above 10 cells (the highest being 17 cells per cubic millimeter) in 3 (2 per cent). The cells were all lymphocytes.

Colloidal Gold Test.—The colloidal gold reaction was determined on 55 samples of fluid and was normal in all of them. For the purpose of this report a reading of less than 2 (lilac) in any tube is reported as a negative reaction.

COMMENT

This study indicates that only 25 per cent of patients with delirium tremens have an abnormally high pressure of the cerebrospinal fluid. The vast majority of our patients had a normal pressure, thus invalidating the generalization that there is an increase of pressure in delirium tremens. If one considers that it is difficult to relax properly the patient with delirium tremens for accurate determination of the pressure of the cerebrospinal fluid even under the most favorable conditions, then the probability is enhanced that more than 75 per cent of such patients will have normal pressures.

These observations agree with those of Merritt and Fremont-Smith,⁸ who examined the cerebrospinal fluid of 108 patients with acute alcoholic intoxication and found normal pressures in 75 per cent of the series. Likewise, Rosenbaum, Herren and Merritt¹⁰ found normal pressures in 75 per cent of a series of 201 patients suffering with acute alcoholism (including, but not limited to, patients with delirium tremens).

In the aforementioned study by Rosenbaum, Herren and Merritt, about 20 per cent of the series had a slightly increased protein content in the cerebrospinal fluid. However, in the present study only 5 patients (3 per cent) had an increased concentration of protein in the cerebrospinal fluid. This apparent discrepancy probably is due to the fact that the patients in this series had had drainage of the cerebrospinal fluid with an average removal of 35 cc., while the patients examined by Rosenbaum, Herren and Merritt had had diagnostic taps only, with about an average removal of 10 cc. of cerebrospinal fluid. The protein content of the cerebrospinal fluid may be lower in the present series because the cerebrospinal fluid was diluted by ventricular fluid. This finding agrees with the well known fact that the protein content of cerebrospinal fluid varies with the site from which it is taken, the upper limits of protein in ventricular fluid being 15 mg., in cisternal 25 mg. and in lumbar 45 mg.⁹

The fact that the present study reveals the cerebrospinal fluid to be normal in the vast proportion of patients with delirium tremens does not preclude the advisability of performing spinal taps in such cases. The therapeutic advantages of such taps are doubtful,¹¹ but the diagnostic advantages are made apparent by the fact that in 7 cases in this series the diagnosis of an injury to the head was made in this manner. Adequate examination of spinal fluids revealed the presence of syphilis of the central nervous system in another 7 cases. Hence spinal taps are advocated for diagnostic purposes and not on the basis of reducing a hypothetical increased pressure of the cerebrospinal fluid.

CONCLUSION

The cerebrospinal fluid is normal in 75 per cent of patients with delirium tremens.

46 to 75.....	5	3
Total.....	184	100

were made according to the Ayer, Dailey and Fremont-Smith⁸ modification of the Denis and Ayer method. The colloidal gold test was done according to the method of Lange, as described by Cockrill.⁹

RESULTS

Pressure.—Reliable readings were obtained in 211 cases (table 1). The pressure of cerebrospinal fluid was less than 180 mm. of water in 154 (73 per cent) and above 180 mm. in 55 (27 per cent). In only 5 cases was the cerebrospinal fluid pressure above 300 mm. of water.

Protein.—Protein determinations were made on 184 samples of fluid. They were below the accepted upper limits of normal, namely 45 mg. per hundred cubic centimeters of fluid, in 179 instances (97 per cent) and greater than 45 mg. in 5 instances (3 per cent) (table 2). There were 56 samples of fluid which had low values, being below 20 mg.

Cells.—Cell counts were recorded on 178 samples of fluid. The count was 5 cells per cubic millimeter or below in 168 fluids (94 per cent), between 6 and

Clinical Notes, Suggestions and New Instruments

MAGNIFICATION OF SPERMATOZOA BY MEANS OF THE ELECTRON MICROSCOPE

PRELIMINARY REPORT

FRANCES I. SEYMOUR, M.D., AND MOSES BENMOSCHE, M.D., NEW YORK

Progress in physics and chemistry governs the development of modern medicine. From the time of Leeuwenhoek and his first successful microscope in the seventeenth century, man has been slowly penetrating deeper into the secrets of nature. It is a long cry from Leeuwenhoek's microscope to the binocular microscope with magnifications of 900, 1,500 and 2,000 diameters. Today we are on the eve of amazing discoveries which, in their importance and significance, rival those of William Harvey and Pasteur. The science of medicine is being revolutionized daily. Molecules which not long ago were theoretical entities are now clearly visualized by the electron microscope.

The ordinary refractive microscope revealed nothing more concerning the morphology of spermatozoa than the contour of the head and number and approximate length of tails. All the finer details were hopelessly concealed. Fundamentally, we know little about spermatozoa, and that little may be summed up as (1) motility or nonmotility, (2) general appearance of spermatozoa as seen with magnifications under 2,000 and (3) the numbers of spermatozoa per cubic centimeter of volume of semen. These observations were at one time the only criteria available. It is hardly feasible to think that by looking down from a mountain top into a valley many miles distant one may discern the features of the people and animals inhabiting it. Spermatozoa have presented just such a problem.

For many years it was assumed that motile spermatozoa were fertile. This assumption has since been discredited. Some authors have represented the body of the spermatozoon as being absent, just a head and a tail. Others have stretched their imagination to draw complicated spirem arrangements in the midsections. To obtain the photographs the following method was used:

In order to photograph a specimen through the electron microscope the specimen must be placed in a vacuum. It is therefore necessary to give this specimen added support to avoid disintegration. The microscope is operated with a current varying from 30,000 to 60,000 volts. The specimen of semen from which a spermatozoon was examined and photographed (which photographs are here reproduced) was 0.5 cc. in volume. This was placed in an ordinary test tube and diluted with distilled water to 15 cc. One drop of this specimen was then placed on a fine wire mesh screen, the wire being $\frac{1}{320}$ inch in diameter. This screen was previously prepared in the following manner:

In a reservoir of distilled water having an outlet in the bottom center, the tiny film of collodion was floated. A small piece of screen mesh was placed over the opening. After a few minutes, in which time the collodion evaporated, the water was very carefully siphoned from the glass dish and the collodion film rested on the mesh. The specimen was then ready to be introduced into the vacuum chamber of the microscope. It is interesting to note that the collodion supports the specimen in such a manner that it can be photographed or observed "for periods of from five weeks to three months." The magnification of the original photograph from which figure 1 was reproduced was 13,500 diameters, and of figure 2, 27,000. The pictures were taken on March 31. There are a number of points of interest which can be seen at these magnifications.

This is offered as a preliminary report, made possible through the courtesy of the R. C. A. Electronic Research Laboratories with the help of Dr. Zworykin and Dr. Ramberg and the Cooperation of Mr. Pipher, Mr. Rhea, Mr. Volino and Mr. Ray.

The patient whose spermatozoa have been magnified through the electron microscope is a normal man of 32, the father of four children, the youngest being 6 months of age. It may be assumed, therefore, that the spermatozoon here illustrated is fertile and has been observed by the ordinary microscope at a magnification of 900 diameters. The motility was of high index and the longevity was eighteen hours. It can be further concluded that the spermatozoon was what is considered normal.

Human spermatozoa at this magnification in the electron microscope are so large that to photograph one spermatozoon it is necessary to take three separate pictures. This was accomplished by moving the slide while observing the spermatozoon through a large fluorescent screen in the viewing chamber. The magnification may then be adjusted to the desired value. The definition obtained in the small negative is sufficiently fine to allow enlargement up to any magnification desired. Figure 1 is a composite picture taking in the whole spermatozoon after reconstruction from three separate and distinct photographs. Figure 2 is the head and neck.

Measurements taken from a photographic enlargement are given solely for the purpose of showing the ratio of the different parts:

Head: Width at widest part, 7 cm. (from vertex to neck 11 cm.).

Fig. 1.—Human spermatozoon as viewed with the electron microscope. The original from which this illustration was reproduced was magnified 13,500 diameters. This is a composite of three separate pictures.

Body: Length, from neck to tail, 12 cm.

Tail: Length, from body to what appears to be the termination of the tail, 112 cm.

The head is shaped like a pear. The vertex presents a crater-like notch. The structure within this notch is somewhat less opaque than the main structure of the head, which is completely opaque down to where it vignettes into the body of the spermatozoon. Around the lower end of the "pear" appears a spongelike substance which is contiguous with a similarly appearing structure which runs along the entire length of the body.

The body appears to be a segmented structure, averaging nine to twelve segments in the specimens examined. This body of the spermatozoon is probably the structure, which under the refractive microscope appears as a narrow strip and which was known as the neck. Throughout the length of the body runs a core which is approximately uniform in diameter. This core is distinguished from the rest of the body by its opacity, being denser than the segmented structure around it. The core becomes the tail.

The core of the body surrounded by a narrow margin of substance, similar in opacity to the substance of the body segments, constitutes the tail. On the composite photograph, for a length of approximately 20 cm. from a point where the body terminates, the degree of opacity is apparently uniform.

The opacity then begins gradually to lighten for an approximate distance of 9 cm., where the opacity increases in density over a distance of approximately 9 cm., where it again becomes less dense and continues so throughout the remaining length of the tail. A delicately denser core runs through the length of these two lighter areas, which also show several small, dense, isolated buckshot-like bodies. The tail does not terminate abruptly but breaks up into a blurred, nondescript smudge.

In view of the number of details as revealed in a spermatozoon magnified 27,000 diameters by means of the electron microscope, opening up as this does an entirely new field of experimental research, it can be safely predicted that future investigations will undoubtedly clear up old problems, change our present conceptions of them and create new ones of which we now at present are totally unaware.

The apparent segmentation of the body probably accounts for the extraordinary motility of the head of the spermatozoon as it is propelled in a forward movement. The shape of this part of the spermatozoon has never been so clearly seen before. The crater-like notch on the vertex of the head may very well be some form of suction apparatus to facilitate the penetration of the ovum. With motion pictures we have seen how the

Fig. 2.—Head of human spermatozoon. The original from which this illustration was reproduced was magnified 27,000 diameters.

head of the spermatozoon penetrates the ovum as the first stage of fertilization. This is the first time such a definite irregularity in the structure of the head of the spermatozoa has been seen. As research in these higher magnifications goes on, we may have to throw overboard the old theories of chemotaxis and revamp much of what was heretofore believed true.

COMMENT

1. The belief that a spirem formation existed in the body of the human spermatozoon is not confirmed in this examination.
2. The old conception of the neck must now be changed. We are forced to call the neck the body of the spermatozoon, which appears as a highly complex and segmented structure.
3. There appears to be a heretofore undiscovered but definite irregularity at the vertex of the head of the spermatozoon which may be a distinct organ, such as a suction apparatus.
4. The tail is apparently a great deal longer than has been previously supposed, and it contains variations in structure which may be functional in character.
5. It is possible that the penetration of the spermatozoon into the ovum is effected by means of a specialized apparatus situated at the vertex of the head of the human spermatozoon.

LEGAL RESPONSIBILITY FOR MEDICAL MALPRACTICE

III. FORGOTTEN ANCESTORS OF THE AMERICAN LAW OF MEDICAL MALPRACTICE

HUBERT WINSTON SMITH, A.B., M.B.A., LL.B.
Member of the Bar of the United States Supreme Court
BOSTON

This is the third of a series of six articles on "Legal Responsibility for Medical Malpractice." The two previous articles were published in The Journal March 8 and May 10, respectively.

In *Hodgson v. Bigelow*, 1939 (7 Atl. [2d] 338), the Supreme Court of Pennsylvania held that a physician's failure to give tetanus antitoxin for a "puncture" wound may constitute civil malpractice. In tracing the genealogy of this important American decision I found its early ancestors to be of English blood.

In the year 1553, Anthony Fitzherbert¹ published his "Natura Brevium," in which is contained the first intimation of the novel principle that one may become liable to another for negligent conduct which constitutes no breach of contract. This augury of a new basis in English law for fixing liability on careless conduct not only presaged the monumental development of tort law, which rose to a position of legal preeminence with the advent of the industrial revolution; it pointed out the way for modern doctrines of medical responsibility. One finds that the following passage which is quoted recurs in the arguments of counsel in English malpractice cases. One finds it alluded to in American decisions as well, even as late as the opinion of the Supreme Court of Pennsylvania in 1853 in the case of *McCandless v. McWha* (22 Pa. 261). Singularly, it deals not with the action of a physician but with the careless conduct of a blacksmith. The "Writ de Trespass sur le Case"² reads:

But if a smith prick my horse with a nail, I shall have my action upon the case against him, without any warranty by the smith to do it well; and the writ shall be, wherefore he fixed a certain nail in the foot of a certain horse of J. at N. by which it became corrupted, so that the same horse for a long time could not labour, and he the said J. during that time lost the profit of his horse aforesaid, to the damage etc. For it is the duty of every artificer to exercise his art rightly and truly as he ought.³

In 1615, there came before the remarkable Sir Edward Coke, "father of the common law," at the time

1. La nouvelle Natura brevium du Juge tresreverend Monsieur Anthoine Fitzherbert, London, Richard Totell, 1553.

In the preface Fitzherbert said: "In every Art and Science there are certain rules and foundations to which a man ought to give credit, and which he cannot deny."

"In like manner there are divers maxims and fundamentals in the knowledge of the common laws of the land, which a man ought for to believe very necessary for those who will understand the same law, especially at the beginning of their studies; for upon those fundamentals the whole law doth depend."

Any earlier pertinent materials of the common law are embalmed in the court French of the Year Books. Because of doubts as to the accuracy with which these precedents were recorded and their inaccessibility, English courts and counsel have let them lie there, with only occasional erudite allusions to the Abridgements.

2. Ibid., p. 214, D.

3. "If one retains counsel, and gives him his fee to assist him in the purchase of such a manor, if he becomes counsel for another, or discovers his counsel, case lies; yet though he warrants his client that he shall have the manor, but fails therein, yet if he does his endeavor, case does not lie; for perhaps he could not have the manor, i. e., it was impossible." (11 Henry VI, 24.55.)

chief justice of the Court of King's Bench, the case of *Everard v. Hopkins*,⁴ from which comes the following passage:

In a special action upon the Case, the plaintiff in his declaration shews, that the defendant being a common Chyrurgeon, had undertaken the cure of his servant, being hurt with a cart-wheel; he shews farther, that he was not only careless of the cure (he being by promise and agreement between them, to have 5 Marks for the same cure) but he had also applied unwholesome Medicines, and with them had put him to more pain, per quod servitium suum amisit, per spatium of one whole year; unde actio.

Coke, Chief Justice said:

It is also here laid, that he did apply, indebita and insalubria Medicina; for this the master may have an action clearly; but the servant cannot have an action upon this agreement, but he may have an action upon the case for his applying of unwholesome medicines to him. It is considerable, whether the master here may have an Action upon the Case, upon an Action upon the Case, this he may have, if the master sends his servant to pay money for him upon the penalty of a bond! and in his way a smith, in shoeing, doth prick his horse, and so by reason of this the money is not paid; this being the servant's horse, he shall have an action upon the case for the special wrong which he had sustained by this, by the non-payment of his money, occasioned by this. . . .

Observe that the ratio decidendi of the case is that a master who has contracted with a physician may recover damages for negligent administration of medicine to his servant. Remarks as to the servant's right of action were unessential to the decision and so constitute mere dictum. Sometimes, however, the dictum of today becomes the law of tomorrow. Such was this case; the dictum that the servant, though a stranger to the contract of employment, had an independent action against the derelict physician on the ground of negligence became law by force of later cases (*Pippin v. Sheppard*, 11 Price 400; *Gladwell v. Steggall*, 8 Scott, 60; 5 Bing. N.C. 733; *Longmeid v. Holliday* [Court of Exchequer 1851] 6 Exch. 761 [dictum]).

There is current in some quarters a false notion that only the "quack" need be concerned with mala praxis. How unsubstantial this belief is can nowhere be better illustrated than in the celebrated English case of *Slater v. Baker and Stapleton* (Common Bench), Michaelmas Term, 8 Geo. III, 1767, 2 Wilson 359. This was a special action on the case against a surgeon and an apothecary for unskilfully disuniting the callus of the plaintiff's leg after it was set.

The facts were these. Slater broke both bones of one leg. A local surgeon set them and attended the patient for nine weeks. By the end of four weeks, callus had formed, and soon after the injured man was beginning to walk a bit with crutches. But a protuberance had arisen, and Slater called in Stapleton, a local apothecary, to remove the bandage from his leg. Stapleton declined to do it himself and prevailed on Slater to call into conference defendant Baker, for twenty years first surgeon of St. Bartholomew's Hospital in London. Evidently Baker was not satisfied with the result, for on his third visit he brought with him a new contrivance of his invention for extending the leg, which he applied without obtaining Slater's consent to its use or to the breaking of the callus and resetting of the bones. One reads:

The defendants came to the plaintiff, Baker took up the plaintiff's foot in both his hands and nodded to Stapleton, and then Stapleton took the plaintiff's leg upon his knee, and the leg gave

a crack, when the plaintiff cried out to them and said "you have broke what nature had formed;" Baker then said to the plaintiff, "You must go through the operation of extension," and Stapleton said, "we have consulted and done for the best."

The leg did not reunite as anticipated, and the plaintiff, who was left with a poorer result, sued both Stapleton and Baker.

Other surgeons called as witnesses testified variously that to disunite the callus was not customary except when the leg as set was very crooked; that the way of making it straight was by compression and not by extension. They had not the least idea of the instrument spoken of for extension. Some said they would not have disunited a hard callus even on the patient's request and that in no case would they do so without his consent. All agreed that Baker was eminent in his profession. One reads further:

A woman called as a witness swore, that when the plaintiff came home he could walk with crutches; that the defendant Baker put on to the plaintiff's leg a heavy steel thing that had teeth, and would stretch or lengthen the leg; that the defendants broke the leg again, and three or four months afterwards the plaintiff was still very ill and bad of it. The jury awarded a verdict of £500 against the defendants jointly.

The defendants moved that the verdict ought to be set aside; a part of their contention read:

Baker has been above 20 years the first surgeon in St. Bartholomew's Hospital, reads lectures in surgery and anatomy, and is celebrated for his knowledge in his profession as well as his humanity; and to charge such a man with ignorance and unskilfulness upon the records of this court is most dreadful. All the witnesses agreed Mr. Baker does not want knowledge, therefore this verdict ought not to stand.

The whole court, in an opinion upholding the verdict and affirming the judgment, said:

When we consider the good character of Baker, we cannot well conceive why he acted in the manner he did; but many men very skilful in their profession have frequently acted out of the common way for the sake of trying experiments. Several of the witnesses proved that the callus was formed and that it was proper to remove plaintiff home; that he was free from pain and able to walk with crutches. We cannot conceive what the nature of the instrument made use of is: Why did Baker put it on, when he said the plaintiff had fallen into good hands, and when plaintiff only sent for him to take off the bandage? It seems as if Mr. Baker wanted to try an experiment with this new instrument.

2dly, It is objected, that this is not the proper action, and that it ought to have been trespass vi et armis.⁵

In answer to this, it appears from the evidence of the surgeons that it was improper to disunite the callus without consent; this is the usage and law of surgeons: then it was ignorance and unskilfulness in that very particular, to do contrary to the rule of the profession, what no surgeon ought to have done; and indeed it is reasonable that a patient should be told what is about to be done to him, that he may take courage and put himself in such a situation as to enable him to undergo the operation. . . . For anything that appears to the court, this was the first experiment made with this new instrument; and if it was, it was a rash action, and he who acts rashly acts ignorantly: and although the defendants

5. The plaintiff had a clearcut cause of action for the battery arising from the breaking of his leg, to which he had not given his consent, and for this immediate, intended contact trespass vi et armis was the appropriate action. To support it the plaintiff would not need to prove negligence but only lack of consent and consequent injury.

But in this instance plaintiff sued in "case," and to support this form of action he needed to prove negligence; so the court was confronted with the interesting question: Can an intentional, unauthorized act toward a patient sufficient to constitute "battery" at the same time constitute "negligence"? The answer is yes when the omitted consent is to an experimental treatment attended with risk of failure and is therefore, in the view of the medical profession, improper to apply without prior consultation of the patient.

Today in such cases the plaintiff usually proceeds on the theory of battery, because of the fewer elements required to make proof.

4. *Everard v. Hopkins* (Court of Kings Bench) 1615, 2 Bulst. 332; 1 Roll. Rep. 124; 80 E. R. 1164.

in general may be as skilful in their respective professions as any two gentlemen in England, yet the court cannot help saying, that in this particular case they have acted ignorantly and unskilfully, contrary to the known rule and usage of surgeons.

This case illustrates several interesting points:

1. The eminence of the practitioner and the purity or benevolence of his motive afford no defense to a civil action for malpractice. This follows because the object of the action is not punishment of the physician for moral turpitude but compensation for an injury caused by medical dereliction. The actionable violation of the patient's right of personal integrity may consist of either intentional or negligent conduct.

2. One who collaborates, even in a minor role, in the culpable act, as did Stapleton in holding the leg, becomes equally liable in damages as a "joint tortfeasor." Pending opportunity to give deserved comprehensive attention to the important question of joint responsibility in medical transactions, the general rule may be stated thus: It is possible for two physicians to be called in to treat the same patient concurrently and yet for neither to be liable for the lack of skill or the negligence of the other. They have a right to make such division of the medical service to be rendered as, in their sound judgment, circumstances require. In such case each, in serving with the other, is held answerable for his own medical conduct and for all wrongful acts or omissions of the other that he observes and permits to continue without protest or which, using reasonable diligence, he should have noticed; but this, in main, is the limit of his liability. (*Morey v. Thybo*, 199 Fed. 760, 118 C.C.A. 198, 42 L.R.A. [N.S.] 785).

3. Though one might suppose that by submitting himself to treatment a patient thereby impliedly consents to any procedure which the physician deems appropriate and administers in good faith, this assumption is too broad. In respect to unusual procedures the physician should disclose his intention and preferably put before the patient the alternatives, the intended purpose and a fair statement of the risk, all with a view to enabling the patient to make a fair choice and to give his actual consent.⁶ It may be well to bear in mind two types of cases: (1) those in which a physician wishes to try a novel or experimental remedy not yet applied as a medical measure to the treatment of human beings, even though its value has been demonstrated by animal experimentation and laboratory tests and even though in the opinion of the user it is intrinsically sound, and (2) all cases in which some procedure is proposed which is calculated to effect radical alteration of the status quo, with an element of appreciable risk, such as certain operations or the administration of drugs involving a substantial hazard of tissue damage or of profound constitutional reactions. The latter cases are not so clearcut as those in group 1, but they demand thought as to whether bare consent of the patient is enough to warrant going ahead with the procedure. In *Theodore v. Ellis* (Supreme Court of Louisiana, 1917) 75 So. 655, it was held that a first drainage operation for a disorder of the bladder was warranted under a broad consent from the patient but that subsequent

lobectomy of the prostate gland, when the surgeon had not made a full disclosure of the nature of the operation and its purpose, was not.

This obligation of disclosure has a reasonable basis in fair play toward the patient. But it rests even more solidly on the duty of disclosure springing (1) from the relationship of trust and confidence between physician and patient, which partakes of a fiduciary character, and (2) from the obligation an expert may owe to a novice. Usually parties deal at arm's length, and neither owes the other the benefit of his superior knowledge ("caveat emptor"). But when one person is an expert in possession of technical information necessary to the enlightened decision of a novice who justifiably relies on him for guidance, a duty to disclose material facts may arise. The case is even stronger in regard to the physician, for it may be argued that his very employment is in part as a counsellor on health. An interesting analogy exists in the law of trusts. If A conveys property to B, as trustee, for the use and benefit of C, a trust is created. B, for purposes of administering the property, has the full authority incident to possession of the legal title (similar to that of a physician whose general control is authoritative in managing the health of the sick patient). The trustee can negotiate ordinary transactions in the interest of the trust without consulting C, the beneficiary, who holds the equitable title. But if he proposes any unusual investment or any action which may threaten dissipation of the corpus (principal or "body" of the trust), he must make a full disclosure to the beneficiary and obtain his informed consent before he takes such action. Otherwise he is responsible for consequent injury.

4. *Slater v. Baker* shows that what is "due care" and what is negligence in medical practice is a question of fact, determinable by the jury in each new case. The jury is to be guided by the testimony of expert witnesses as to what the average practitioner at the time and the place of the conduct would consider prudent or bad practice.

5. Lastly, it stands for the now well established principle that when the plaintiff's action is based on the defendant's failure to use due skill in a particular transaction, evidence as to the skill the defendant used in treating other patients is not admissible.⁷

A case which has been much more cited both in America and in England than its intrinsic value merits is that of *Seare v. Prentice*, decided in 1807 by Lord Ellenborough, then chief justice of the King's Bench⁸ (8 East, 347; 103 E.R. 376). Seare, a shoemaker, brought an action on the case against the defendant, Prentice, whom he had employed as a surgeon, for negligently, ignorantly and unskilfully reducing his dislocated elbow and fractured arm. At the trial, Justice

7. Results of similar treatment of other patients has probative value and is admissible when defendant's professional capacity is put in issue or a claim is made that the very method of treatment itself was medically improper.

6. Substantial reasons may legally justify nonobservance of the normal duty to disclose. For instance, suppose a person is so ill that his life can be saved only by a drug the administration of which is itself attended by some risk, such as sulfanilamide for a patient with streptococcal septicemia due to otitis media. The patient is of nervous temperament or so prostrate that disclosure of the danger might precipitate a fatal crisis. The drug may be administered without disclosure of the risk involved.

8. It was he who decided the remarkable case of *Ashford v. Thornton*, 1 Barn. and Ald. 405, (1818). Richard Thornton, on jury trial at Warwick, was found "not guilty" of the murder of Mary Ashford, whereupon her brother, William Ashford, sued out an appeal of murder against him. Appellee Thornton, when he was brought into the Court of King's Bench, pleaded viva voce, "Not guilty, and I am ready to defend the same by my body," and taking a gauntlet from his right hand, he threw it on the floor. Judge Ellenborough reviewed the ancient common law precedents and was forced to conclude that no change had been made in the almost forgotten rule that "the mode of trial by law in such a case of appeal is by 'battle,' at the election of the appellee except where the appellee is an infant or a woman or above sixty years of age." He declared: "The law of the land is in favour of the trial by battle, and it is our duty to pronounce the law as it is, and not as we may wish it to be." There was great excitement at this prospect of a trial by combat, and the public expected to see the battle fought out before the judges at the Tothill Fields; but Ashford, being more resolute in the law than in the Tothill Fields, refused to proceed further, and the appeal was dismissed. The case lists, occasioned a sensation and resulted in the statute of 59 Geo. III C. 46, which abolished criminal appeals and trials by battle in writs of right.

Heath instructed the jury that unless negligence was proved they could not investigate the want of skill. Since the evidence did not substantiate negligence, a verdict was brought in for the defendant, under direction of the judge. In reviewing the proceedings, Lord Ellenborough found that the defendant was entitled to a verdict because "no want of skill was imputed to the defendant," but he condemned the dictum of the trial court that unless negligence was proved the jury could not investigate the want of skill. Since, as he confessed, the question did not arise on the evidence, it follows that Ellenborough's own remarks on the subject are themselves mere dictum, because unnecessary to a decision of the case, but they have been cited often. One reads:

... an ordinary degree of skill is necessary for a surgeon who undertakes to perform surgical operations; which is proved by the case of Wilson, and indeed by all analogous authorities; in the same manner as it is necessary for every other man to have it in the course of his employment; as the farrier who undertakes to cure my horse must have common skill at least in his business, and that is implied in his undertaking; and although I am ready to admit that a surgeon would be liable for crassa ignorantia, and would be justly responsible in damages for having rashly adventured upon the exercise of a profession, without the ordinary qualification of skill, to the injury of a patient: yet the question did not arise upon the evidence in this case; for no want of skill was imputed to the defendant: and therefore the opinion of the learned Judge upon that point does not affect the merits of the verdict upon the evidence in the case.

English lawyers sometimes assert that this case was the first to lay down the rule that a physician must use skill as well as care. I have shown, however, that "unskilfulness" was made the basis of decision in the earlier English case of *Slater v. Baker and Stapleton* (1767) and was recognized as far back as Roman law.⁹

Many courts, today, speak of negligence and failure to use due skill as separate legal entities. Actually, they can mean by so doing only to break down negligent conduct of a medical case into causal components. The various deficiencies which may result in a negligent performance may be represented as follows:

1. X is ignorant, lacking in education or specific information necessary for the particular undertaking.

Example.—X, who has operated only on the abdomen and never familiarized himself with surgical procedures on the brain, in a nonemergency in a city where competent brain surgeons are available essays a difficult operation on the brain. He is unable to complete it successfully because of failure to foresee the necessity for certain special instruments and precautions.

Though he uses all the care and skill he has, the very assumption, unnecessarily, of an undertaking beyond his preparation is negligent and permeates the entire conduct of the case.

But note: the law is interested in his incapacity primarily because of the injury done to the patient through the resulting inability to conduct the case properly. If the same surgeon, despite his poor qualification, completes the operation successfully, his undertaking the task still remains "negligent" by common usage but not in law, because the treatment itself, the actual conduct of the case, is free from fault. The physician has acted at his peril, but the ominous dangers threatened by his rash assumption to act have not materialized.

2. X is well informed as to theory but lacks in requisite experience and so in the skill demanded by the undertaking.

Example: A recently graduated medical student who has not taken a surgical internship or had actual experience is profoundly versed in the literature on surgical operations on the brain. He essays a (nonemergency) operation on the brain, believing he can duplicate one of the operations which he has seen Dr. Harvey Cushing do or one of which he has read descriptions. The operation fails for want of skill.

3. X has information and experience, but due to inaptitude he has never acquired the skill possessed by the "average practitioner" in his community.

Example: A practitioner of long standing fails to reduce and set a Colles fracture with the skill which the average practitioner would employ. Marked deformity results.

4. X has information, experience and skill but fails to apply skill to the particular case, with consequent injury.

Example: X knows that aminopyrine is a dangerous drug but prescribes it freely for persistent headache without making periodic studies of the blood or carefully checking the clinical response. Full-blown granulocytopenia develops in the patient.

5. X has information, experience and skill but in a transaction not requiring skill fails to use such care or diligence as the average practitioner would apply.

Example: X abandons the care of a patient with a simple ailment without legally terminating the relationship of physician and patient. In consequence, a preventable complication develops which the average practitioner in attendance could have prevented.

6. X has knowledge, judgment, care and skill but fails to apply average judgment to the transaction.

Example: A child under 2 years of age is admitted to a hospital with osteomyelitis and shows evidences of acute infection and septicemia, profound dehydration and shock; the surgeon performs an immediate, radical surgical operation, which precipitates death. In the face of contraindications which would invariably deter the average surgeon, precipitate action without clinical basis may involve negligence, however carefully and skilfully the operation is performed. In this case the basis is failure to exercise average judgment.

7. X has knowledge, judgment, care and skill but fails to maintain control of the medical transaction; or he entrusts properly delegable functions to one he reasonably should have known to be incompetent.

Example: X, in carrying out an abdominal operation, relies on "green" nurses, pressed into emergency service, to make the count of the sponges used, without personally verifying its accuracy. A retained sponge causes tissue necrosis.

Example: While conducting a vitally important investigation of a patient's renal function, X delegates the laboratory work to Y, an independent laboratory technician (an independent contractor), whose results have several times been found undependable. Y negligently arrives at erroneous conclusions. As the result of the normal reports, the patient is subjected to a contraindicated operation. X had reasonable notice of Y's incompetence; it was therefore negligent to entrust the investigations to her or, in the alternative, to accept her results without verification.

Note: 1. In all of these instances, the dereliction may lie either in an affirmative act (misfeasance) or

9. Smith, H. W.: Legal Responsibility for Medical Malpractice: I. The Legal Matrix of Medical Malpractice, J. A. M. A. 116:942 (March 8) 1941.

in an omission to act when there is a duty to do so (nonfeasance). In the presence of a physician-patient relationship, whether the omitted action is negligent depends on whether a prudent physician would have considered neglect to do the omitted thing as bad practice. The mere fact that he himself, in like circumstances, would have done the omitted thing is not enough: he might have considered it wise through an abundance of caution, while current practice would not have considered the omission as culpable.

2. In each case, the standard of knowledge, judgment, care or skill which the practitioner must bring to bear is that which the average practitioner of his own class and community would apply under similar circumstances.

3. There may be combinations of two or more of these seven causes of negligent conduct of a case.

One of the most influential statements of principle in respect to the law of malpractice occurred in the charge to the jury given by Tindal, chief justice, in the English case of *Lanphier and Wife v. Phipos* (cases at nisi prius), 1838, 8 Carrington & Payne, 475.

The facts were these. Mrs. Lanphier, in September 1835, while traversing a field became alarmed at the spectacle of an approaching cow, gave a sudden turn, tripped and fell on the wrist of her right hand, causing "a fracture of the small bone of the arm, and a partial dislocation of the third bone of the palm of the hand." The defendant was called and arrived within an hour after the fall. A neighbor, testifying for the plaintiff, declared she expressed the opinion to the physician that the wrist was injured but that he took hold of the patient's hand and then gave a contrary opinion. He said the injury was not in the wrist but in the arm, put splints on and bound it from below the elbow to the wrist, leaving the hand hanging down. Swelling gradually increased, and vinegar was applied by the defendant's direction, and he expressed his opinion that "it was doing very well." The witness drew his attention to the increase of swelling and inflammation, and he removed the splints and examined the arm; whenever she spoke to him on the subject, he expressed the opinion that it was doing very well. The splints were kept on for about seven weeks. The inflammation spread to the shoulder, and the husband was alarmed and complained, so the defendant sent some kind of oil to bathe it. The witness told him that if it were hers (Mrs. Jones's) she would not be satisfied with the way in which it was progressing; but he still said he thought it was doing very well. When the defendant had attended the patient about seven weeks, she retained a new surgeon, V. He applied longer splints, which supported the hand, and instituted special treatment to reduce the inflammation; but despite improvement, the patient lost the use of her hand, so that she could not use a knife or fork or dress or undress herself with it.

On these facts, at the trial, Mr. Calloway, of Guy's Hospital, and Mr. Tyrrell, of St. Thomas's Hospital, were allowed to give their opinions.

Both considered that defendant's treatment of the case was injudicious, particularly in suffering the hand to hang down, and in not making sufficient efforts, by lotions and other means, to reduce and keep down the inflammation.

For defendant, Mr. Luke of the London Hospital, who examined the injury in June 1937, under a judge's order, testified that in his opinion there had not been any mismanagement on the part of the defendant and that such was the opinion of the second surgeon, V. Three other surgeons, after hearing

Mr. Luke's evidence of what he discovered and ascertained on the examination, expressed it as their opinion that the defendant was not at all to blame.

Tindal, chief justice, in summing up, after stating the pleadings, charged the jury as follows:

What you will have to say is this, whether you are satisfied that the injury sustained is attributable to the want of a reasonable and proper degree of care and skill in the defendant's treatment. Every person who enters into a learned profession undertakes to bring to the exercise of it a reasonable degree of care and skill. He does not undertake, if he is an attorney, that at all events you shall gain your case, nor does a surgeon undertake that he will perform a cure; nor does he undertake to use the highest possible degree of skill. There may be persons who have higher education and greater advantages than he has, but he undertakes to bring a fair, reasonable, and competent degree of skill, and you will say whether, in this case, the injury was occasioned by the want of such skill in the defendant. The question is, whether this injury must be referred to the want of a proper degree of skill and care in the defendant or not. The action is not brought for any injury sustained by the husband, but it is brought by the wife for the injury which she has sustained by the loss of the use of her hand. The husband must be joined in the action, but the damages are to be given for the injury sustained by her. His Lordship then read and commented on the evidence, and then left the case to the jury, who found a verdict for the plaintiff. Damages £100.

In surveying English common law, one feels constrained to see what Blackstone said on the subject. In his "Commentaries on the Laws of England"¹⁰ is this passage:

4. Injuries affecting a man's health are where, by any unwholesome practices of another, a man sustains any apparent damage in his vigour or constitution. As by selling him bad provisions, or wine; by the exercise of a noisome trade, which infects the air in his neighborhood; or by the neglect or unskilful management of his physician, surgeon, or apothecary. For it hath been solemnly resolved, that mala praxis is a great misdemeanour and offence at common law, whether it be for curiosity and experiment, or by neglect; because it breaks the trust which the party has placed in his physician, and tends to the patient's destruction.

The learned Blackstone stated the rule correctly but erred as to its reasons. He said the physician's dereliction is a misdemeanor, resting on a "breach of trust." I have shown, on the contrary, that the usual basis is civil and that at common law medical responsibility springs partly from "contract" (an implied warranty by the physician in accepting employment that he possesses average qualifications) and partly from "tort" (especially doctrines of negligence). Both of these bases of liability rest on principles of compensation for injury rather than of punishment for a delict. Later it will be seen that of these two the "tort" basis is of greater importance. A neighboring passage suggests that Blackstone fell into error because he was thinking of the Roman law.

The precedents which have just been surveyed have a peculiar interest as the earliest "blood ancestors" of the present law of malpractice both in England and in the United States. Their intrinsic worth also warrants attention, for their doctrines are still law. They have been added to and elaborated by the later cases but not overturned. They have been left behind, but they still point the direction in which the law is traveling.

GLANDULAR PHYSIOLOGY AND
THERAPY

ADRENAL CORTEX INSUFFICIENCY

ROBERT F. LOEB, M.D.

Professor of Medicine, Columbia University
NEW YORK

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the author and do not necessarily represent the views of the Council.—Ed.

CLINICAL PICTURE OF ADRENAL CORTEX
INSUFFICIENCY

The syndrome of adrenal cortex insufficiency was first described by Thomas Addison, in his classic treatise, published in 1855. This symptom complex as observed in Addison's disease is characterized by an insidious onset and progressive development of fatigability and asthenia to the point of utter exhaustion, associated with varying degrees of anorexia, nausea and vomiting. Very occasionally diarrhea and abdominal pain are present. The symptoms may appear in the course of weeks, months or even years. At times, however, the tempo of the disease may be greatly accelerated. This may occur either spontaneously or in response to a withdrawal of sodium salts from the diet, or in association with an acute infection, and may, in the course of a few days, terminate fatally. These abrupt episodes of adrenal insufficiency are termed "crises." In a few instances the symptoms and signs of hypoglycemia may dominate the clinical picture, particularly among patients receiving salt or desoxycorticosterone acetate therapy.

Pigmentation and arterial hypotension are the physical signs usually exhibited by patients with adrenal cortex insufficiency. The pigmentation is brownish and may be either diffuse or blotchy in distribution. It is most typically observed in the mucous membranes of the buccal cavity. However, there are patients in whom no pigmentation develops. Hypotension is almost invariably present among patients seeking medical aid, but under emotional stress the blood pressure may momentarily rise to normal or even to abnormal levels. During crises it falls to strikingly low levels, and the patient presents a picture of dehydration and shock.

PATHOLOGIC PHYSIOLOGY

In the past decade great advances have been made in the clarification of certain mechanisms involved in the development of adrenal cortex insufficiency. These have been discussed extensively elsewhere in this series, but, since they constitute the basis of present therapy, it is essential that those with clinical significance be considered briefly at this point.

Salt and Water Metabolism.—In 1927 Baumann and Kurland¹ and Marine and Baumann² showed that the sodium concentration in the blood of adrenalectomized cats was decreased and that a solution of sodium

chloride prolonged life more effectively than did solutions of other electrolytes or of dextrose. In 1932 and 1933 it was shown by the writer³ that the concentration of sodium in the blood of patients suffering from uncompensated adrenal cortex insufficiency was decreased and that replacement of the sodium ion relieved this condition. It was also shown that withdrawal of the sodium ion from the diet of patients with Addison's disease precipitated acute adrenal cortex insufficiency.⁴ It was then observed in dogs that the loss of sodium following adrenalectomy results from increased excretion of sodium ions by the kidney.⁵ These observations have been amply confirmed,⁶ and Harrop and associates⁷ and Allers⁸ independently pointed out that adrenalectomized dogs could be maintained in good health indefinitely if sodium salts were administered in sufficient amounts, particularly if the potassium content of the diet was reduced. A disturbance in water metabolism is intimately related to that of the concentration of sodium ions in adrenal cortex insufficiency. Thus, there is a tendency for water to be lost as the insufficiency progresses up to the point where a fall in blood pressure causes oliguria.⁹ This is associated with a consistent decrease in plasma volume. However, water is not, as a rule, lost from the body as rapidly as is sodium. This is shown by the fact that the sodium concentration of the blood decreases. It has been shown that acute adrenal cortex insufficiency may be induced in a patient with Addison's disease by restricting the intake of fluid, despite the administration of salt. Under these conditions a crisis associated with a fall in blood pressure, collapse and a decrease in plasma volume without a decrease in blood sodium appeared in a patient studied by Willson and Sunderman.¹⁰ A loss of sodium without a decrease in plasma volume, i. e., without a simultaneous loss of water, does not regularly give rise to the picture of adrenal cortex insufficiency.

Potassium Metabolism.—An increase in the concentration of the potassium ion was first observed in animals by Baumann and Kurland,¹ in 1927, and in human subjects with adrenal insufficiency by the writer in 1932.³ This disturbance is closely related to disturbances in sodium and water metabolism. In general, as sodium is lost from the body, potassium in the blood serum tends to increase and the ability of the body to excrete potassium ions is impaired. Kendall and associates¹⁰ and Zwemer and Truszkowski¹¹ empha-

sized the susceptibility of adrenalectomized animals to the injection or ingestion of potassium salts. Wilder and his collaborators¹² emphasized the danger attendant on the ingestion of large amounts of potassium salts by patients with Addison's disease. Despite the deleterious effects of the potassium ion in adrenal cortex insufficiency, the concept that death from this insufficiency results from potassium poisoning is untenable.

Renal Function.—Marshall and Davis¹³ were the first to point out, in 1916, an increase in nonprotein nitrogen in the blood of adrenalectomized animals. In patients with adrenal cortex insufficiency an increase in nonprotein nitrogen, inorganic phosphorus and sulfate may occur. Furthermore, decreases in urea clearance may be present even in the absence of nitrogen retention. These disturbances have been shown by Stahl, Kuhlmann and Urban¹⁴ to be associated with hemoconcentration and presumably with a decrease in renal blood flow. Observations on creatinine clearance in adrenal cortex insufficiency by Margitay-Becht and Gömöri¹⁵ led to the same inference. The disturbances in electrolyte and water metabolism already discussed are to a large extent referable to a derangement of normal renal activity¹⁶ other than that resulting in decreased renal blood flow. It seems probable that this derangement is related to tubular reabsorption.

Carbohydrate Metabolism.—Porges,¹⁷ in 1909, was the first to report the presence of hypoglycemia in patients suffering from Addison's disease and in adrenalectomized animals. In recent years the studies of Britton and Silvette,¹⁸ Long and his colleagues¹⁹ and Kendall and his associates²⁰ have shown that a decrease in glycogen storage in the liver and in sensitivity to insulin are also characteristic of adrenal cortex insufficiency.²¹ The disturbances in carbohydrate metabolism vary considerably in different species, and they vary greatly in intensity in persons with Addison's disease, but they may be of sufficient gravity to prove fatal. It is generally believed that the abnormalities of carbohydrate metabolism result from a decrease in the utilization of carbohydrate and a decrease in gluconeogenesis.²² The disturbances in carbohydrate metabolism as seen in Addison's disease vary independently of the disturbances in salt and water metabolism.²³ It has been amply established by the work of Long and asso-

ciates,¹⁹ Thorn,²⁴ Kendall^{20a} and our own laboratory²⁵ that various steroids isolated from the adrenal cortex exhibit striking differences in their effect on carbohydrate and electrolyte metabolism.

Nitrogen Metabolism.—Nitrogen retention and a decrease in the excretion of ammonia appear in the development of severe adrenal cortex insufficiency and are probably in part due to decrease in renal blood flow. Following the administration of various extracts of adrenal cortex there is often a temporary increase in the urinary excretion of nitrogen perhaps due to improvement in renal function. On the other hand, it has been shown by Long and co-workers¹⁹ and Kendall and his associates^{20a, b} that the nitrogen excretion of diabetic rats or of fasting normal rats may be increased by the administration of certain adrenal steroids. This increase has been shown to be due to gluconeogenesis from body protein, which may be the primary effect, but which possibly arises in response to a decrease in the utilization of carbohydrate.

Adynamia.—This manifestation of adrenal cortex insufficiency, which plays a major part in the subjective manifestations of Addison's disease, has been extensively studied by Ingle²⁶ in rats. From the results of his work it is certain that adynamia results chiefly from the disturbances in carbohydrate metabolism and to a lesser extent from the loss of salt and water and decrease in blood flow. Whether or not other factors play a part is not known.

Arterial Hypotension.—The fall in blood pressure to shock levels during crises of adrenal cortex insufficiency is dependent to a large extent on the disturbances in salt and water metabolism. The chronic but milder degrees of hypotension may also be dependent on the same abnormality, since the blood pressure may be raised by the administration of sodium salts as well as by the administration of desoxycorticosterone acetate, which primarily affects the metabolism of salt and water. Whether other factors contribute to hypotension is not known.

Miscellaneous Disturbances.—Among these, pigmentation occupies a prominent position. This abnormality, although not universally present in Addison's disease, is extremely common, yet its mechanism remains totally obscure. Sensitivity to change in temperature, particularly to cold, and sensitivity to pain stimuli, which are characteristics of patients and animals in adrenal cortex insufficiency, may possibly be correlated with the disturbances in carbohydrate and in electrolyte metabolism, as indicated by the studies of Kendall.^{20a} The moderate lowering of the basal metabolic rate occasionally observed is probably on a similar complex basis. The mechanisms acting in the production of hypercalcemia, elevation of serum phosphatase, retention of bromsulphalein and gynecomastia, all of which are sometimes present in Addisonian patients, are not known. Focal and diffuse neurologic disorders in adrenal cortex insufficiency result probably from hypoglycemia or from decreased cerebral blood flow or from both.

In 1933 Swingle and collaborators²⁷ suggested that a hormone of the adrenal cortex had an effect on the

peripheral vascular bed. The evidence provided was not convincing. However, the fact that an extract of the adrenal cortex may effect prompt relief in dogs suffering from severe adrenal cortex insufficiency without causing demonstrable changes in the blood volume or the electrolyte pattern²⁸ suggests the possibility of action either on tissue of the nervous system or perhaps on the capillaries. Furthermore, Menkin²⁹ has recently shown that extract of adrenal cortex inhibits the dilatation of capillaries which usually results from the cutaneous injection of leukotaxine or exudates. The significance of these observations in relation to adrenal cortex insufficiency is not yet apparent.

TREATMENT OF ADRENAL CORTEX INSUFFICIENCY

The treatment of adrenal cortex insufficiency and that of diabetes mellitus have much in common. In both diseases therapy should be directed toward (1) the specific replacement of the hormone or hormones lacking, (2) the correction of the physiologic disturbances resulting from hormonal deficiencies and (3) the avoidance of those factors known to intensify the abnormalities present. The treatment of adrenal cortex insufficiency as exemplified by Addison's disease is also analogous to that of diabetes in that often a few simple measures suffice to control the disease, whereas at times the failure to institute vigorous therapeutic measures promptly may result in a fatal outcome which might have been avoided. Thus, in a patient whose symptoms and signs of adrenal cortex insufficiency are mild, ingestion of a moderate amount of salt in addition to that present in the diet, moderate limitation of the potassium content of the diet, avoidance of extremes of heat and cold, as well as avoidance of mental and physical strain, may be adequate to maintain moderately good health for months or years. On the other hand, when a crisis develops either in the natural course of the disease or because of salt withdrawal, diarrhea, acute infection, surgical intervention or other factors, an immediate intensive attempt to restore base and water by all possible means becomes imperative to avoid fatal peripheral circulatory collapse.

In recent years the treatment of Addison's disease has been advanced materially through (1) the introduction of salt therapy, (2) the restriction of potassium salts, (3) the elaboration of extracts of the adrenal cortex and (4) the synthesis and availability of desoxycorticosterone esters. The role of each of these must be considered in detail.

Role of Salt and Diet.—With the ingestion of 7 to 20 Gm. of salt in addition to that of the diet, many patients with Addison's disease can be restored to moderately good health for months or years, as stated. Most of these patients take their salt in enteric-coated 1.0 Gm. tablets distributed at frequent intervals during the course of the day. Others prefer to take their salt in the form of an approximately 1 per cent solution. Only a few are able to tolerate capsules. Wilder and associates have suggested that part of the sodium be taken in the form of citrate or bicarbonate to avoid chloride retention. In the writer's experience this has rarely proved necessary.

It should be pointed out that before the advent of desoxycorticosterone many patients in severe addisonian crises recovered as a result of the parenteral adminis-

tration of liberal amounts of physiologic solution of sodium chloride. This treatment not only restored base but also lowered the blood potassium and nonprotein nitrogen to normal, improved renal function, raised the blood pressure and relieved peripheral circulatory collapse.

Wilder and his associates¹² have properly advocated the restriction of potassium in the diet of the salt-treated patients with adrenal cortex insufficiency, and Sister Mary Victor³⁰ has carefully outlined the technic of the preparation of this type of diet.³¹ In view of the capricious appetites of most patients with Addison's disease, the rigid restriction of the intake of potassium becomes more a theoretical than a practical consideration. In patients who cannot be maintained in good health through the ingestion of large amounts of salt and moderate restriction of the intake of potassium, treatment with desoxycorticosterone esters is indicated. The treatment of hypoglycemic episodes occurring in Addison's disease is best accomplished by the ingestion of a glass of orange juice or two lumps of sugar. If the patient is unable to cooperate, 50 cc. of a 25 per cent solution of dextrose may be given intravenously. Infusions of large amounts of dextrose are apt to give rise to hyperglycemia, followed in the course of two to four hours by a recurrence of hypoglycemia.

Desoxycorticosterone Acetate.—Since Steiger and Reichstein³² synthesized desoxycorticosterone, this natural steroid of the adrenal cortex has become available for the treatment of patients and has initiated a new era in the therapy of adrenal cortex insufficiency. This particular substance, as has been suggested in another chapter, affects almost exclusively electrolyte and water metabolism, as has been demonstrated by the studies of Thorn and his associates,³³ and Cleghorn and his co-workers,³⁴ Levy Simpson³⁵ and Loeb and his collaborators³⁶ (shown in the accompanying chart). It causes striking retention of sodium salts with restoration of the blood sodium level to normal. It also causes retention of water with increase in plasma and interstitial fluid volume and consequent gain in weight. It lowers the serum potassium, at times to abnormally low levels, and temporarily increases the excretion of this ion. It restores renal function and increases the excretion of nitrogen when nonprotein nitrogen has been retained. Desoxycorticosterone esters also cause a decrease in the concentration of total protein, calcium

and cholesterol in the serum, probably because of the hemodilution associated with an increase in plasma volume.

There are great variations in the responses to desoxycorticosterone esters in patients suffering from adrenal cortex insufficiency. These are important to recognize and as yet impossible to anticipate. For example, in studies at the Presbyterian Hospital,^{30b} in New York, one patient became markedly edematous and gained 11 Kg. in ten days, during which time he received 10 Gm. of salt a day and 19 mg. of desoxycorticosterone propionate daily. On the other hand, another patient receiving the same diet and the same amount of salt gained but 2 Kg. in thirty days, during which time he received 25 mg. of the same synthetic product each day. Normal persons on this regimen gain but minimal amounts of weight.

The arterial blood pressure of patients with Addison's disease who are treated with desoxycorticosterone esters rises. In conjunction with salt solution administered

disturbances of electrolyte and water metabolism, just as it may appear in patients receiving adequate amounts of salt alone. Recent studies³⁷ of patients receiving other steroids of the adrenal cortex, e. g., corticosterone and compound E of Kendall, as well as cortical extract, indicate that massive doses of these substances have some effect on carbohydrate metabolism. Unfortunately, the amounts of these steroids necessary to produce a significant effect are not available for clinical use, and the amount of cortical extract required to elevate the blood sugar and prevent hypoglycemia is in most cases almost prohibitive.

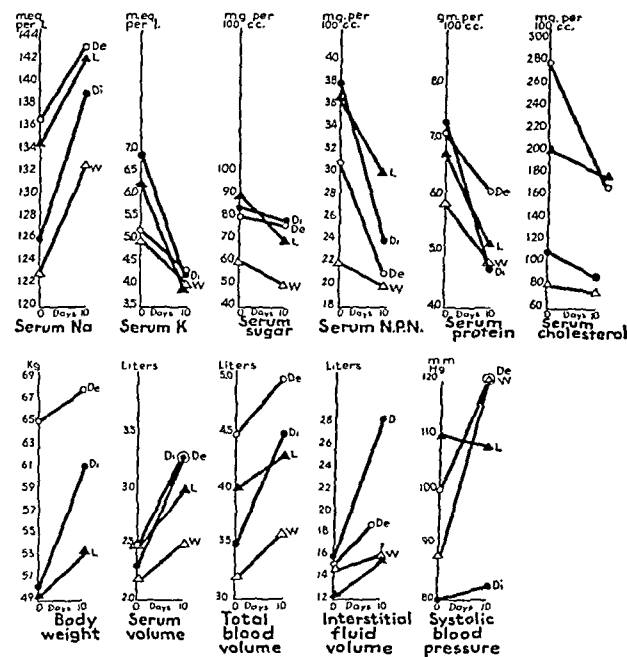

There is no definite evidence that the pigmentation of the patient with Addison's disease is influenced by desoxycorticosterone esters. It is true that patients under treatment with the synthetic compound and salt appear lighter in color, but it seems likely that this change should be ascribed to rehydration rather than to depigmentation. I have not seen pigment spots in the oral mucous membranes disappear under any form of treatment. Possibly more definite knowledge concerning pigment metabolism will be forthcoming when patients have been under treatment for longer periods.

Subjectively, desoxycorticosterone esters tend to increase the sense of well-being, the strength, the appetite and the outlook on life of patients with Addison's disease. A number of patients resume work, and many others are able, from the standpoint of strength, to take up normal activities. It must be remembered, however, that the majority of patients with Addison's disease suffer from tuberculous infection, and this constitutes a therapeutic problem in itself.

Administration of Desoxycorticosterone Esters.—

Two general technics for the treatment of adrenal cortex insufficiency with desoxycorticosterone acetate or propionate have been developed. Thorn and his co-workers^{33a} and Levy Simpson^{33c} have prepared and implanted subcutaneously, with great success, pellets of a crystalline preparation (synthetic desoxycorticosterone acetate). Others³⁸ have administered desoxycorticosterone esters subcutaneously or intramuscularly in solutions of peanut or sesame oil. Desoxycorticosterone is only sparingly soluble in water and is essentially without effect when patients with Addison's disease take it by mouth.

The preparation of pellets for implantation presents two problems. The first is that of sterility, which is difficult to obtain, because high temperatures destroy the compound. The second problem is concerned with the pressure under which pellets are prepared. If they are too solidly packed, their solubility is slight. If they are too loosely packed, absorption is apt to be irregular and, indeed, if they crumble, absorption may be very rapid, and serious overdosage may ensue. Thorn^{33a} has prepared and standardized his pellets so that from each is dissolved 0.3 to 0.4 mg. of desoxycorticosterone acetate daily. After the daily requirement of the substance is determined in the patient with Addison's disease who takes about 4 Gm. of salt a day in addition to that of a normal diet, by means of daily subcutaneous injections of desoxycorticosterone acetate, the pellets are implanted subcutaneously below the scapula. Enough pellets are used so that the number implanted will yield about two thirds of the subcutaneous requirement. This procedure allows a margin of safety in that if the pellets produce symptoms or signs of overdosage, the salt intake may be reduced. If the

Effects produced in patients with Addison's disease in ten days by a desoxycorticosterone derivative. These patients received large doses, i. e., about 190 mg., during the initial ten days of treatment.

during crises, the drug may cause a rise in pressure from shock levels in the course of a few hours. In other patients the rise in blood pressure may be gradual over a period of two to four weeks. At times hypertension may appear. Thus, in four of the patients studied by us there has been a rise in blood pressure to 175/100, 160/92, 160/110 and 146/108 respectively. Whether or not these patients had underlying hypertensive disease, masked by Addison's disease, is not known. It is also not known whether the rise in blood pressure is dependent on factors other than the correction of the disturbances of electrolyte and water metabolism.

An important fact to be borne in mind is that desoxycorticosterone esters have no demonstrable effect on the carbohydrate metabolism of patients with Addison's disease. No definite effect on the fasting blood sugar, dextrose tolerance curves or respiratory quotients has been observed. Furthermore, spontaneous and severe hypoglycemia may appear in patients receiving enough synthetic desoxycorticosterone to correct

37. Thorn,²¹ Ferrebee and others.²³

pellets are not quite enough to maintain the sodium concentration of the blood at a normal level, the salt intake may be increased, or supplementary doses of desoxycorticosterone acetate may be injected, or more pellets may be implanted.

When patients are treated with daily subcutaneous injections instead of pellets, they are trained in the technic of injection as are diabetic patients who take insulin. The patients in our experience^{36b} do best on a normal diet of average salt content, and the dose of desoxycorticosterone ester is adjusted under these conditions.

Patients should be under close observation during the regulation of their dosage. They should be weighed daily and their blood sodium, serum protein, potassium, nonprotein nitrogen and sugar should be determined initially if possible. The vital capacity, the venous pressure and the size of the heart as determined by roentgen examination should be observed from time to time, as these examinations and auscultation of the chest afford the best evidence of impending cardiac insufficiency, a complication occasionally occurring in the course of treatment.

The maintenance requirements of desoxycorticosterone acetate or propionate vary greatly in different patients. In our series the dose necessary to maintain the normal blood electrolyte pattern has varied from 1 mg. to 7 mg. daily.

In the presence of a crisis or at the beginning of treatment in the presence of moderately severe insufficiency, larger doses may be required for two or three days. A dose of 15 mg. may perhaps be given safely twice a day, provided the patient is carefully watched for evidence of overdosage. In the presence of a severe crisis the administration of desoxycorticosterone acetate should be supplemented by one or two daily infusions of 1,500 cc. of physiologic solution of sodium chloride until the patient is able to take food and fluid by mouth. No further definite rules can be advanced for the treatment of the patient in a crisis, as the desoxycorticosterone and salt requirements differ widely not only in different patients but also in the same individual at different times.

Surgical Procedures.—Before the advent of desoxycorticosterone acetate, major surgical operations in patients with Addison's disease almost invariably proved fatal. At the present time an operation may be undertaken with comparative safety if the disturbances of electrolyte and water metabolism are first corrected with synthetic desoxycorticosterone. No specific regimen for anteoperative therapy can be outlined, but in some instances the injection of 25 mg. of desoxycorticosterone acetate four hours before operation and perhaps 1 liter of saline solution serves to prevent serious depletion and consequent shock. In the postoperative period the patient must be watched for evidence of adrenal cortex insufficiency, including hypoglycemia, as well as for manifestations of overdosage. The amounts of desoxycorticosterone and salt must be adjusted to these indications.

Complications.—Desoxycorticosterone esters which produce the striking salutary effects described in patients with adrenal cortex insufficiency may at times give rise to dangerous complications. Among the first 18 patients whom we³⁶ treated with the synthetic substance at the Presbyterian Hospital there were 15 in whom edema developed, varying from transient puffiness of the face or ankles to massive anasarca. In 5 of these patients there developed also varying degrees of

respiratory distress and a sense of tightness of the chest associated with roentgen evidence of dilatation of the heart, predominantly on the right side. In some of these patients there occurred an elevation of venous pressure, roentgen and clinical evidence of pulmonary congestion and a decrease in vital capacity. Cardiac insufficiency developing as a consequence of desoxycorticosterone therapy has been observed also by others. This complication of therapy is fortunately reversible in most instances but may prove fatal. The mechanisms responsible for the development of cardiac insufficiency have not been definitely established. Arterial hypertension cannot be of great importance, as congestive failure appeared in 3 patients in whom the systolic pressure was below 110 mm. of mercury. An increase in plasma volume and a decrease in the serum potassium concentration may be of importance. It is of interest that Ragan,³⁹ at the Presbyterian Hospital, has been able to produce cardiac dilatation in adrenalectomized dogs by massive doses of desoxycorticosterone acetate and sodium chloride, but he has observed no effect in normal animals.

Not only have patients under treatment with desoxycorticosterone esters suffered from varying degrees of cardiac insufficiency, but in our series 6 of 20 patients given this therapy in the last twelve months have died. Of these, 1 died of cardiac insufficiency, 1 died of disseminated tuberculosis and 1 died at home presumably of adrenal cortex insufficiency when the dose of the synthetic compound was reduced excessively for the relief of mild symptoms of cardiac insufficiency. Two other patients died suddenly at home without the cause of death being determined. Finally, a patient died suddenly while under observation in the hospital. She had mild cardiac insufficiency and mild hypoglycemia (blood sugar 62 mg. per hundred cubic centimeters). Her blood sodium and potassium had been normal three days before death, and at autopsy no adequate cause for her sudden demise was determined. Our experiences are entirely similar to those recently reported by Wilder³⁸ and by Thompson and co-workers.⁴⁰

Thus, it is apparent that while desoxycorticosterone therapy has proved exceedingly useful, it is not devoid of danger. Furthermore, it should not be considered a panacea in the treatment of the numerous disturbances present in adrenal cortex insufficiency. It has been shown to have no demonstrable effect on carbohydrate metabolism in patients with adrenal cortex insufficiency and no definite effect on pigmentation. It does not completely relieve the symptom of adynamia, as might be anticipated from Ingle's study.²⁶ Finally, a number of patients, apparently adequately controlled from the standpoint of electrolyte and water metabolism, died rather suddenly and for no obvious cause. Excessive doses of desoxycorticosterone cause a periodic paralysis associated with a sharp decrease in blood potassium. This paralysis is relieved by the administration of potassium chloride. It is possible that sudden weakness appearing in patients treated with synthetic hormone may, at times, have a similar basis.

Adrenal Cortex Extract.—Commercial preparations of adrenal cortex have, in large amounts, been shown to have definite effects on water and electrolyte⁴¹ as

41. Thorn, G. W.; Garbutt, H. R.; Hitchcock, F. A., and Hartman, F. A.: The Effect of Cortin on the Sodium, Potassium, Chloride, Inorganic Phosphorus and Total Nitrogen Balance in Normal Subjects and in Patients with Addison's Disease, *Endocrinology* **21**: 202 (March) 1937.

well as carbohydrate metabolism. The effects are, however, small, and it seems unlikely, as stated before, that these extracts in the doses usually administered have significant clinical value. On theoretical grounds, extract of adrenal cortex should prove of greater value than desoxycorticosterone, as it contains other steroids which are known to have greater and more diversified action, particularly in relation to carbohydrate metabolism. Unfortunately, the concentrations of these steroids are not sufficiently high to prove of real value in small doses. On the basis of our studies²⁵ it does not seem probable that doses of less than 5 cc. of cortical extract contain clinically significant quantities of steroids that would affect the carbohydrate metabolism. Consequently, the injection of 5 cc. amounts of extract, even in conjunction with the administration of desoxycorticosterone acetate, does not seem indicated in the maintenance of the patient.

Despite these criticisms, it seems probable that 50 to 75 cc. at least of commercial extract given in divided doses in the course of twenty-four hours in addition to saline infusions and with repetition of the dosage the next day may prove more satisfactory in treating serious crises than will desoxycorticosterone acetate alone.

Although cortical extracts have been shown to be active when administered by mouth, the amounts necessary are probably at least 3 to 4 times that of the parenteral dose. Consequently oral administration is of doubtful clinical value.

Studies on adrenalectomized animals have shown that a number of preparations of adrenal cortex extract have demonstrable potency when administered orally. Pfiffner and his co-workers^{41a} estimated that 10 cc. of their preparation given by mouth was equivalent to about 1 cc. given parenterally. Thorn^{41b} demonstrated that the glycerin extract of 1,000 Gm. of adrenal glands administered by mouth daily to a 10 Kg. adrenalectomized dog maintained the animal in good health. Grollman^{41c} has also reported activity of a charcoal adsorbate of adrenal cortex extract. On the basis of these and similar findings the oral administration of extracts has been recommended in the treatment of patients. In view of the relative inactivity of the usual cortical extracts administered parenterally in doses of 5 cc. or less, it is unlikely that considerably larger amounts given by mouth have any significant therapeutic effect. The observations of the writer support this view. Thus one patient was given oral doses of a commercial glycerin extract costing from \$5 to \$15 a day over a period of some months. The extract was given in addition to salt and had little if any clinical effect. This patient's disease is now easily controlled by small doses of desoxycorticosterone acetate. Another patient whose disease was controlled both by desoxycorticosterone acetate in doses of 1 to 2 mg. daily and by about 15 Gm. of salt was given 15 tablets of an oral preparation in conjunction with vitamin C daily. When the salt intake was reduced to 5 Gm. a day, symptoms of acute insufficiency developed in three days with a fall in sodium from 136 to 129 m. eq. per l. despite the large dose of oral extract. A third patient taking 6 tablets of the same preparation and 3 Gm. of salt a day in addition to her diet was admitted to the hospital because of progressive weakness, anorexia and

nausea. Her blood sodium on admission was 124.8 m. eq. per liter. A single infusion of salt solution, the discontinuation of the oral cortical extract preparation and an increase in the daily salt intake to 12 Gm. a day for four days resulted in clinical improvement associated with a rise in blood sodium to 135 m. eq. per liter. It is the writer's opinion that, in the presence of established adrenal insufficiency, cortical extract given by mouth has no place in treatment, particularly now that desoxycorticosterone acetate is available.

Numerous attempts have been made to transplant an adrenal gland or the cortical cells of a gland from one person to another in the treatment of Addison's disease. These efforts have not met with success up to the present time, and the procedure is not to be recommended. Ingle has devised an ingenious method for the successful transplantation of the adrenal glands of a newborn rat into another young rat, but this procedure is so far only of academic interest. Auslender⁴² has recently reported successful heterotransplants of adrenal cortex free from medullary cells. These observations have not been confirmed.

TREATMENT OF MISCELLANEOUS CONDITIONS

Preparations of the adrenal cortex have been employed in recent years in the treatment of various conditions ranging from nonspecific fatigue to surgical shock. At the present time it is difficult to appraise the value or wisdom of administering these preparations in the absence of demonstrable adrenal cortex insufficiency, since their continued administration is known to cause atrophy of the adrenal glands of normal animals.⁴³ However, Perla and his co-workers⁴⁴ have offered evidence suggesting that anteoperative treatment with saline solution and desoxycorticosterone acetate prevents surgical shock, and Scudder⁴⁵ has advocated the use of large quantities of extract of adrenal cortex in the treatment of that condition. These studies receive theoretical support from the observations of McAllister⁴⁶ and of Ragan and his associates.⁴⁷ These workers have shown that desoxycorticosterone esters administered three to six hours before operation prevent the usual decrease in plasma volume accompanying ether anesthesia and surgical operation.

Weil and Browne⁴⁸ reported that the urinary substances protecting young adrenalectomized rats from the fatal effects of exposure to cold are not excreted by normal human beings but appear in the urine following febrile illnesses and other forms of stress. Although the significance of this report is not yet apparent, it does not justify indiscriminate administration of preparations of the adrenal cortex.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING CHAPTER, WHICH IS THE SIXTH OF A SERIES ON AMPUTATIONS AND ARTIFICIAL LIMBS TO APPEAR IN THIS COLUMN. WHEN COMPLETED, THE SERIES WILL BE PUBLISHED IN THE FORM OF A HANDBOOK ON AMPUTATIONS. THE COUNCIL WISHES TO EXPRESS ITS APPRECIATION FOR THE COOPERATION OF ITS GROUP OF CONSULTANTS ON ARTIFICIAL LIMBS. THE COUNCIL IS REPRESENTED BY DRs. FRANK D. DICKSON, HARRY E. MOCK, FRANK R. OBER, S. PERRY ROGERS, PAUL STEELE AND PHILIP WILSON, AND THE ASSOCIATION OF LIMB MANUFACTURERS OF AMERICA IS REPRESENTED BY MESSRS. MCCARTHY HANGER SR., W. E. ISLE, JOSEPH A. SPIEVAK, DAVID E. STOLPE AND J. B. KORRADY.

HOWARD A. CARTER, Secretary.

CHAPTER II—SECTION V

REAMPUTATIONS AND SECONDARY OPERATIONS

Careful adherence to the general principles involved in amputations will prevent or lessen the need for reamputations. Nevertheless, in the hands of the best surgeons reamputation is occasionally necessary. Reoperations on the stump are more often needed. The following conditions are the commonest causes for these secondary operations and reamputations:

1. *Sloughing or Ulceration Over the End of the Stump.*—In spite of the most careful technic the posterior fascial flap, in leg amputations, may become detached from the bone, leaving the tibia covered only by skin. Ulceration at this point occurs and sloughing may result in leaving a portion of the tibia exposed. Again infection occasionally develops in the soft tissues of the stump, necessitating removal of sutures and retraction of the skin and fascial flaps with resulting exposure of the end of the tibia. In lower leg amputations done because of circulatory disease or for diabetes, one cannot use too long an anterior flap lest it tend to undergo necrosis along its margin. It is exceedingly difficult to do plastic skin operations on a stump with the bone thus exposed. It is far wiser to reopen the stump by cutting away the ulcerated portion and reforming the best possible flaps, saw away the exposed portion of bone and treat it as one would at a primary amputation. Reamputation of the fibula at a suitable level, reinjection of exposed nerves and religation of major vessels are indicated. These complications usually arise in leg stumps which were originally cut too long, so that reamputation frequently provides a stump capable of better function than the original. When the stump is 8 or 10 inches below the knee, the reamputation may be performed 3 to 5 inches higher, thus providing better flaps with a better selection for the location of the scar. Fortunately a stump 5 or 6 inches in length gives better healing and better leverage for the use of the prosthesis than does the original 8 or 10 inch stump. There is less tendency toward sloughing of the flap when the original operation is performed in these higher sites. The usual mistake which so often necessitates these reamputations is our effort to leave a long lower leg stump.

2. *Cutaneous Defects Over the Sides of the Stump.*—When the ulceration occurs on the side of the stump and not directly over the bone, it is usually caused by impairment of circulation due to too tight a flap. It may also be due to pressure of a socket on soft tissues that are too bulky or redundant. Such areas may be dissected away, allowed to form a good granulation bed and then skin grafted. Skin grafts are satisfactory, however, only if the area is one not subjected to pressure within the socket. Plastic operations with the formation of pedicled flaps from skin adjacent to the stump may be used, provided the site of the pedicled graft can be closed by primary suture and is not itself subjected to pressure from the socket. Pedicled grafts from the opposite extremity are occasionally indicated. Unless infection is very mild or absent, the site of defect must be carefully cut away and the wound allowed to granulate and become healthy before the graft is applied. Redundance of skin and soft tissues may be excised and closed by primary suture with excellent results provided the scar is placed at a point not subjected to pressure within the prosthesis.

3. *Osteomyelitis or Aseptic Necrosis of the End of the Bone.*—It is unusual for an active, suppurating type of osteomyelitis to occur; an aseptic necrosis or low grade osteomyelitis is more common. A severe infection is opened and packed like any osteomyelitis. In the absence of severe infection, clean excision of all dead tissues and reamputation may be performed. Fresh flaps should be dissected free of their original scars and all important structures dealt with as in a primary amputation. Special care is needed to avoid redundancy of soft tissues.

4. *Neuromas.*—Painful stumps are usually due to nerves caught in scar tissue or to typical neuromas. Seldom is reamputation for this condition necessary. However, when one is convinced that the painful stump is real, exploration of the scars or direct attack on the neuroma is indicated. The offending nerve is carefully dissected from the surrounding tissue, cut away higher up and the end of the nerve injected with absolute alcohol.

5. *Neuroses.*—Neuroses of all descriptions frequently develop with the symptoms referred to the stump or even to the amputated member. True malingering in a case of amputation is exceedingly rare. One must not be too prone to jump to the conclusion that the patient's complaints are of a neurotic order. A minute nerve caught in a scar can give the pain, twitching sensation or even the picture of causalgia so often complained of. Furthermore, reoperations do not always disclose or remove the cause. One must approach these cases with a sympathetic understanding rather than a brusque statement that the patient only imagines the complaint. These cases are problems for both the surgeon and the fitter of the artificial limb, who is often unjustly accused for the complaints. Before considering reamputation because of a painful stump and before recommending the purchase of a new artificial limb for the cure of a similar complaint, one must rule out a true neurosis as the cause of symptoms. Conversely, the surgeon must be very careful in his remarks to the patient complaining of pain in the stump or in his criticism of the prosthesis worn lest inadvertently he sow seeds of neurosis in the mind of a susceptible individual.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

AN APPRECIATION

The Council on Physical Therapy is most desirous of expressing its sincere appreciation to the following consultants who have given so generously of their time and effort during the past year in assisting the Council in its work:

Drs. Fred L. Adair, Howard Ballenger, M. Herbert Barker, Walter M. Boothby, Milton B. Cohen, W. Allen Conroy, Earl C. Elkins, Samuel Feinberg, Hart Fisher, Hubert H. Hathaway, John S. Hibben, Archibald Hoyne, K. K. Jones, Louis Katz, Disraeli Kobak, Arno Luckhardt, Harry E. Mock Jr., C. O. Molander, Tell Nelson, Benjamin Orndoff, S. L. Osborne, George Shambaugh Jr., William O'Neill Sherman, E. M. Smith, Kellogg Speed and Grant E. Ward.

Audiometers and Hearing Aids.—Drs. C. C. Bunch, George M. Coates, E. P. Fowler, Isaac Jones, Douglas Macfarlan, C. Stewart Nash, Horace Newhart, Paul Sabine, B. R. Shurly and W. P. Wherry.

Educational Work.—Drs. Frances Baker, Benjamin Boynton, Muriel Case Downer, F. H. Ewerhardt, Richard Kovacs, Fred B. Moor, W. H. Northway, Walter M. Solomon, Arthur L. Watkins and Walter J. Zeiter.

Röntgen Rays.—Drs. William E. Chamberlain, Arthur C. Christie, E. C. Ernst, Gioacchino Failla, F. M. Hodges, John T. Murphy, Robert C. Newell, Eugene Pendergrass, U. V. Portmann, Lauriston S. Taylor and J. L. Weatherwax.

Artificial Limbs.—Drs. S. Perry Rogers, Paul Steele and Philip Wilson, and Messrs. McCarthy Hanger Sr., W. E. Isle, J. B. Korrady, Joseph Spievak and David E. Stolpe.

Electrocardiographs.—Drs. A. R. Barnes, George Fahr, Harold E. B. Pardee, W. D. Stroud, Carl J. Wiggers and Frank N. Wilson.

NEWMAN THERMO-FLO ACCEPTABLE

Manufacturer: Majestic Surgical Instrument Company, 2608 Cicero Avenue, Chicago.

The Newman Thermo-Flo is designed to be used for the intravaginal application of superheated air. In operation, heated air is circulated through a specially shaped thin-walled rubber bag, which is inserted in the vagina in a collapsed state and then inflated with air so as to distend the vagina. The rubber bag is brought into contact with the tissues, and heat is conducted over a large area to the surrounding tissues.

Newman Thermo-Flo.

The apparatus consists essentially of a fan which circulates air through the applicator bag, an electrical unit which heats the air, a thermostat for controlling the temperature (temperatures up to 130 F. may be obtained), a thermometer which extends through the applicator and into the bag, and a hand-operated rubber bulb used to

inflate the rubber bag. The pressure, approximately $\frac{1}{2}$ to $\frac{3}{4}$ pound, is indicated on the pressure gage mounted on the control panel.

As evidence of its therapeutic usefulness, the firm submitted a summary of the results of 402 cases treated with the Thermo-Flo at a maternity hospital and a detailed report of 71 patients having chronic inflammatory disease of the pelvic organs who were treated with the Thermo-Flo in the department of obstetrics and gynecology of a university hospital.

The maternity hospital reported its results with the Newman Thermo-Flo as follows:

Summary of results with the Thermo-Flo Machine in cases of:

- I. Acute salpingitis—gonorrheal in origin.
- II. Subacute salpingitis—gonorrheal in origin.
- III. Chronic salpingitis: A—with small palpable mass.
B—with large palpable mass.
- IV. Subacute pelvic cellulitis—postpartum and postabortal probably streptococci in origin.
- V. Chronic pelvic cellulitis—postpartum and postabortal in origin.
- VI. Endometriosis.

The following table summarizes the results obtained: (The Roman numerals in the chart correspond to those used in the preceding table.)

Diagnosis	No. of Cases	Good		Fair		Poor		Satisfactory per Cent, Surgery	
		No.	Per Cent	No.	Per Cent	No.	Per Cent	Good or Fair	Per Cent

The report from the university hospital contained the following data:

Results

Group 1

Chronic bilateral salpingo-oophoritis—39 cases

Complete cure	6
Marked improvement	25
Moderate improvement	5
Slight or no improvement	3

Three patients in this group became pregnant after the treatments were completed.

Group 2

Chronic bilateral salpingo-oophoritis with unilateral or bilateral tubo-ovarian masses—13 cases

Complete cure	0
Marked improvement	10
Moderate improvement	1
Slight or no improvement	2

Group 3

Postoperative residual pelvic inflammatory disease—7 cases

Complete cure	1
Marked improvement	5
Moderate improvement	0
Slight or no improvement	1

Group 4

Chronic parametritis—7 cases. (4 postabortal. 2 postpartum, 1 postoperative.)

Complete cure	1
Marked improvement	5
Moderate improvement	1
Slight or no improvement	5

Group 5

Chronic pelvic inflammatory disease (frozen pelvis)—5 cases

Complete cure	0
Marked improvement	4
Moderate improvement	1
Slight or no improvement	0

One patient in this group became pregnant after the treatments were completed.

Summary of Results

Complete cure	57 cases (80.3%)
Marked improvement (included with cases of "complete cure")	
Moderate improvement	8 cases (11.3%)
Slight or no improvement	6 cases (8.4%)

(Interpretation of terms):

Complete cure: Symptomatic and anatomic cure.

Marked improvement: Complete disappearance of symptoms with definite anatomic improvements.

Moderate improvement: Symptomatic improvement with little anatomic regression.

Slight or no improvement: Slight or no improvement either symptomatically or anatomically.

A detailed description of each of the 71 cases was given in the report.

The apparatus was investigated clinically by the Council, and it was found to be satisfactory from the treatment standpoint. The thermostat seemed to control the air temperatures quite well; at any one setting the temperature of the air in the applicator remained stable. The operating temperature is read on the thermometer in the applicator extending into the bag and is regulated by means of the thermostat on the panel.

The Council voted to accept the Newman Thermo-Flo for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. OFFICE OF THE COUNCIL.

CYCLOPROPANE

In 1939 the Council published a report¹ of its consideration of cyclopropane without special reference to any particular brand. On the basis of the evidence available at that time it was pointed out that the gas is a suitable anesthetic agent when used cautiously by those fully informed of its properties, potential dangers and signs which indicate the stages of anesthesia with the agent. It was emphasized that unusual cardiac effects (arrhythmias) are encountered with cyclopropane, that high concentrations of the gas and its combination with sympathomimetic or other drugs which increase such irregularities are to be avoided and that it is therefore essential to watch the pulse carefully during administration. It was further pointed out that the signs to indicate the depth of anesthesia differ from those of Guedel for other anesthetic agents and that, since the respiratory center is not stimulated by cyclopropane, premedication which affects the respiratory rate should be used with caution because these signs may be further obscured by too large doses. It was indicated that, except for difficulty in detecting the plane of anesthesia by those unfamiliar with the agent, the lack of respiratory stimulation and the tendency to produce cardiac arrhythmias and postanesthetic headache, the gas possesses the advantages of decreased pulmonary irritation, effectiveness in concentrations which provide abundant oxygen, less excitement during induction and low toxicity. From the standpoint of chemical and

1. The present Status of Cyclopropane, J. A. M. A. 112: 1064 (March 8) 1939.

physical properties, it was indicated that cyclopropane has the same potential danger of explosibility as the more commonly used ethyl ether.

Since the previous report of the Council was published, additional clinical and pharmacologic studies of cyclopropane have appeared in the literature.²

In general, this further evidence does not alter the previous conclusions of the Council concerning this anesthetic agent. In view of the accumulation of favorable published evidence for the use of cyclopropane as an inhalation anesthetic, the Council was about to give further consideration to a submitted brand of the gas for anesthesia with a view to acceptance when recently reported deaths from explosions of the gas caused the Council to hold acceptance in abeyance pending further investigation of the factors responsible for explosions which have occurred. In the interim cyclopropane had received official recognition under standards included in the U. S. Pharmacopeia (XI, 1939, Second Supplement).

In proceeding with its investigation into the cause of the explosions which have occurred with cyclopropane, the Council recalled that ten years ago a report by Henderson³ under the auspices of the Committee on Anesthesia Accidents of the American Medical Association pointed out that explosions of anesthetic mixtures do not occur unless fired, and that precautions to avoid electrostatic discharges and other potential ignition factors must be taken. The Council also considered the incidence of anesthetic explosions which has been reported by Woodbridge⁴ for ether, ethylene and cyclopropane. This investigator tabulated the results obtained from a questionnaire answered by eighty-seven specialists in anesthesia. The author made no attempt to include all reported explosions in order to secure a representative, unbiased sampling. The explosion rates for these anesthetic agents were found to be respectively 1.73, 2.44 and 3.85 per hundred thousand administrations, but the standard deviations due to chance are of such magnitude that the differences between the rates reported are of no significance. The explosion mortality was found to be only two (one, cyclopropane) for the entire 2½ million cases tabulated.

From information furnished by a consultant of the Council, some of the explosions with cyclopropane which have occurred since its previous report was published (March 8, 1939) are listed in table 1. It should be noted that the list includes five fatalities and does not agree with the Woodbridge⁴ report, in which no attempt was made to include all reported explosions. Previously a note in *THE JOURNAL*⁵ indicated that the

number of explosions from mixtures of anesthetic gases listed in an excerpt of the report of the Subcommittee on Fires and Explosions of the American Society of Anesthetists, Inc.,⁶ probably did not represent all such explosions that have taken place. Study of the available details of the explosions listed in table 1 revealed that those occurring at the University of Michigan and the University of Minnesota had two features in common: the nurse was wearing rubber gloves and the patient was covered with a woolen blanket. The Michigan explosion occurred during the administration of cyclopropane and oxygen diluted with about 50 per cent helium, whereas the Minnesota explosion occurred with a mixture of cyclopro-

pane, oxygen and ether. In the former instance the nonfatal nature of the explosion was attributed to the possibility that the inert gas helium had reduced the force of the explosion. In both instances the production of static electricity was regarded as the immediate cause.

Consideration was also given to reports concerning the use of so-called inert gases as diluents of anesthetic mixtures to eliminate explosive concentrations and of methods employed to avoid conditions conducive to the discharge of static sparks. A report of the U. S. Department of the Interior by Jones, Kennedy and Thomas⁷ presents data obtained with an

explosion-tube apparatus to determine the inflammability of cyclopropane-air-carbon dioxide, nitrogen and helium mixtures, and cyclopropane-oxygen-helium mixtures.

By trial and error the limits of inflammability of the prepared mixtures were determined and averages taken of those mixtures that just propagated and those that just failed to propagate flame. The data obtained for the cyclopropane-air-(nitrogen, helium, carbon dioxide) mixtures show that at least 13.4 volumes of nitrogen are required per volume of cyclopropane to render all mixtures of these gases noninflammable as compared with 14.8 volumes of helium and only 8.0 volumes of carbon dioxide. Although carbon dioxide is thus shown to be superior as a diluent in the prevention of cyclopropane explosions, the authors point out that this obviously cannot be employed in cyclopropane-oxygen anesthetic mixtures because the high concentration required to eliminate explosive hazards of this mixture would produce marked physiologic effects on patients breathing such mixtures. Helium is indicated as the diluent of choice because it is a light gas which can be breathed with less effort than nitrogen, to compensate somewhat for the lowered oxygen content of proposed mixtures, and because gaseous mixtures containing helium are more difficult to ignite by electric discharges than mixtures containing similar percentages of other inert gases. The data presented for the

TABLE 2.—*Promising Mixtures*

Mixture No.	Composition, per Cent by Volume		
	Cyclopropane	Oxygen	Helium
1.....	15	20	65
2.....	20	20	60
3.....	25	25	50
4.....	30	30	40

cyclopropane-oxygen-helium mixtures indicate that all mixtures containing 3 to 60 per cent cyclopropane may be used safely. Those mixtures which appear to offer the most promise for anesthetic use are given in table 2.

The authors point out that the mask, the apparatus and the patient's lungs will contain explosive mixtures for a very short period both at the beginning and at the end of the administration of the anesthetic and that, while the method of admixture with inert gas eliminates the violently explosive mixtures that usually are present through the anesthesia process, the proper procedure has yet to be worked out for administering cyclopropane-oxygen-helium mixtures so that explosive mixtures will not be present in the equipment at any time. It is indicated that an extensive program of chemical experiments with nonexplosive mixtures of gaseous combustible anesthetics is in progress. Haas, Hibshman and Romberger⁸ have reported similar studies and, on the basis that nitrogen is a satisfactory, readily available diluent gas to render cyclopropane-oxygen anesthetic mixtures nonexplosive, have proposed the use of cyclopropane-air-oxygen for anesthesia by means of an air bulb attachment to the breathing bag for the introduction of air into closed anesthetic machines. At the nineteenth annual meeting of the Congress of Anesthetists held in Chicago, Oct. 21-25, 1940, reports by these and the foregoing investigators included tentative methods for the clinical use of nonexplosive mixtures of cyclopropane. The development of a device for anesthetic machines to detect the presence of explosive concentrations during administration was suggested.

More recently Horton⁹ has reported a study of mixtures comprising two anesthetic gases. He is of the opinion that the explosion hazard may be reduced by using mixtures containing cyclopropane, ethylene and oxygen in proper combination. The addition of a fourth gas, such as nitrogen, helium or hydrogen, has been shown to increase the nonexplosive range even further. The use of flame barriers in anesthetic machines to prevent explosion pressures from reaching the patient has been proposed as a third measure to minimize the

explosion hazard of anesthetic gases. Evidence that such barriers are feasible has not as yet been offered.

To avoid conditions conducive to the discharge of static sparks it is necessary to have all objects and people in the operating room at the same electrical potential. An advance in this direction has been made by Horton⁹ in designing the Horton intercoupler, a high resistance coupling device with five terminals to maintain the same electrostatic potential between any five bodies. The use of high resistance intercoupling is based on the previous report by Woodbridge, Horton and Connell.¹⁰ The problem of static electricity is resolved to the elimination of nonconductors between anesthetic machines and operating room tables and floors and the patient and personnel to dissipate electrostatic charges as rapidly as these develop.

It should be kept in mind that the use of diluent gases to eliminate explosive anesthetic mixtures is limited by the extent to which the oxygen concentration of such mixtures may be reduced without interference with physiologic requirements. From the standpoint of explosion, hydrogen should not be regarded as an inert gas. It is further pointed out that nitrous oxide as well as oxygen supports combustion and therefore that, while a nitrous oxide-oxygen anesthetic mixture alone is relatively safe from the standpoint of explosion, it should not be regarded as a safeguard against this hazard when combined with ether, ethylene or cyclopropane. It should be emphasized that with the exception of nitrous oxide anesthesia the explosive potentialities of anesthetic mixtures of cyclopropane are not greater than those of other commonly employed anesthetics and that precautions to avoid this hazard are the same for all other inflammable anesthetic agents. The use of intercouplers or other means to avoid conditions favoring the discharge of static sparks may be an added hazard unless constant vigilance is applied to the proper technic of their use and the control of all other related factors. It is further emphasized that the Council does not, by this report, recognize the use of any specific mixture of gases in the administration of cyclopropane. The use of diluent gases to eliminate explosive anesthetic mixtures of cyclopropane or other anesthetic agents is in the experimental stage and should not take precedence over proper measures to eliminate all ignition factors.

After further consideration, the Council decided that explosions with cyclopropane are not primarily due to chemical or physical peculiarities of the gas itself but, as with other anesthetic agents, are directly attributable to accidental ignition, the conditions conducive to which may be avoided by observance of the necessary precautions. In view of this and the recent advances made toward the elimination of explosive anesthetic mixtures, it was voted that cyclopropane be accepted with all necessary safeguards.

CYCLOPROPANE FOR ANESTHESIA (Ohio Chemical & Mfg. Co.)

The Ohio Chemical and Manufacturing Company was first to submit a brand of cyclopropane for the consideration of the Council. A preliminary report of its consideration of this brand was published in 1936.¹ At that time the Council voted to defer further consideration of the agent until more evidence of its usefulness was available.

Subsequently, with the accumulation of the additional clinical and pharmacologic evidence considered in the further report of the Council on the gas published in 1939 without reference to particular brands, it was voted to accept the manufacturer's brand of cyclopropane provided it emphasize in its advertising that the product be employed only by those who are thoroughly familiar with the anesthetic agent and include an adequate description of the cardiac arrhythmias encountered with its use and a cautionary statement to avoid the simultaneous use of epinephrine or related substances.

9. Horton, J. W.: Hazards in the Use of Explosive Anesthetics, *Bull. Am. Assn. Nurse Anesthetists* 8:285 (Nov.) 1940.

10. Woodbridge, P. D.; Horton, J. W., and Connell, Karl: Prevention of Ignition of Anesthetic Gases by Static Spark, *J. A. M. A.* 113:740 (Aug. 26) 1939.

1. Cyclopropane for Anesthesia (Ohio Chemical & Mfg. Co.), *J. A. M. A.* 106:292 (Jan. 25) 1936.

The Ohio Chemical & Manufacturing Company was asked if it wished to have its brand of cyclopropane reconsidered by the Council under these conditions. The company indicated its desire to have the product reconsidered and submitted its current advertising. The manufacturer stated that this brand of cyclopropane is now prepared in conformance to official standards for the gas which had become available in the U. S. Pharmacopeia (XI, 1939, Second Supplement). The advertising was found to require some revision. Accordingly, the Council was about to recommend acceptance of the product when recent explosions with the gas caused the Council to hold acceptance in abeyance pending investigation into the factors responsible for these accidents. The Council voted, however, to give further consideration to the manufacturer's brand of the gas provided it agreed to revise its advertising and the product was found to conform to the official standards.

The manufacturer was notified of this action of the Council and replied that steps were being taken to devise means to avoid the explosion hazard through the development of methods to eliminate the causative factors. The company indicated that the problem was being approached from two angles—(1) the use of inert gas to eliminate explosive concentration of oxygen in cyclopropane anesthesia and (2) the avoidance of conditions conducive to the discharge of static sparks. The manufacturer submitted revised advertising but offered to withhold printing of this pending the favorable outcome of methods developed to eliminate the explosion hazard.

After further consideration of evidence submitted by the manufacturer and the reports in the literature, the Council decided that the explosion hazard of cyclopropane is not due to peculiarities of the gas itself but, as with other anesthetic agents, is directly attributable to accidental ignition, the conditions conducive to which may be avoided by observance of the necessary precautions. In view of this and the recent advances made toward the elimination of explosive anesthetic mixtures through the use of diluent gases, the Council voted to recognize cyclopropane as an anesthetic agent if used with all necessary safeguards.

In accordance with its decision to accept cyclopropane, the Council has given further consideration to the manufacturer's product. The submitted advertising is found to require only slight further revision. The cooperative attitude of the concern was commended. The Council voted to accept the brand Cyclopropane for Anesthesia (Ohio Chemical & Mfg. Co.) provided advertising is further revised as indicated and the product is found to conform to the standards of the U. S. Pharmacopeia.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

OFFICE OF THE COUNCIL.

CYCLOPROPANE.—Cyclopropanum. —Trimethylene. — C_3H_6 .—"Contains not less than 99 per cent by volume of $CH_2.CH_2.CH_2$."—U. S. P.

For standards see the U. S. Pharmacopeia under Cyclopropanum.

Caution.—Cyclopropane is inflammable and its mixture with oxygen or air will explode when brought in contact with a flame or an electric spark.

Actions and Uses.—Cyclopropane differs from other gaseous anesthetic agents in that the anesthetic-oxygen ratio is reversed—15 per cent of cyclopropane to 85 per cent of oxygen up to the rarely and briefly used 40 per cent of cyclopropane and 60 per cent oxygen. The high anesthetic potency of cyclopropane as compared with other hydrocarbons makes its use advantageous from the standpoint that abundant concentrations of oxygen may be used. There is evidence to indicate that the rate of diffusion of cyclopropane is about twice that of ethylene. Cyclopropane is eliminated less rapidly than ethylene but much faster than ether. Induction and recovery with cyclopropane are therefore slower than with ethylene but more rapid than with ether.

There is some evidence to indicate that cyclopropane affects the autonomic tissue of the heart more than ether or chloroform. In high concentrations it heightens the irritability of this tissue and predisposes to the occurrence of cardiac arrhythmias. This effect has been shown to be enhanced with the simultaneous use of epinephrine. For these reasons the pulse must be carefully observed and the use of sympathomimetic drugs avoided during cyclopropane anesthesia. Cyclopropane does not stimulate respiration as do many other general anesthetic agents, and for this reason preoperative sedation with respiratory depressants must be used with caution. The signs of Guedel for other anesthetic agents do not apply to cyclopropane, so that familiarity with the signs of the stages of anesthesia for cyclopropane is absolutely essential in the administration of this agent.

The explosibility of cyclopropane-oxygen mixtures is not greater than that of other anesthetic-oxygen mixtures with the exception of nitrous oxide, but, since the latter gas also supports combustion, its use with cyclopropane should not be regarded as a safeguard against this hazard. Careful operating room technic to avoid conditions conducive to the production of electrostatic sparks and the presence of open flames and the caution should be observed with the same precautions as those for other anesthetics.

The advantages of cyclopropane consist in its effectiveness in concentrations providing an adequate supply of oxygen, decreased pulmonary irritation, less excitement during induction and low toxicity. Its disadvantages include lack of respiratory stimulation, difficulty in detection of the planes of anesthesia by those unfamiliar in its administration, and tendency to produce cardiac arrhythmias and postanesthetic headache.

Dosage.—Cyclopropane is usually furnished in compressed form in metal containers. In use the gas is passed into an inhalation apparatus of the closed circuit type and is then administered by inhalation from a rebreathing bag, usually with the admixture of oxygen. The concentration employed varies from 15 to 40 per cent and with the individual patient but should probably not exceed 30 per cent. The remainder of the mixture should consist of a minimum of 20 per cent oxygen, but this should be supplied in quantities adequate for physiologic needs. When other anesthetics are used in combination or when premedication has been employed, less cyclopropane is required.

SOLUTION LIVER EXTRACT-LILLY.—A sterile aqueous solution containing the nitrogenous nonprotein fraction G of Cohn et al. preserved with 0.5 per cent phenol. The potency of the preparation is such that its daily parenteral administration has been found to produce the standard reticulocyte response defined for each U. S. P. unit (injectable) present, when assayed in cases of pernicious anemia as required by the Council.

Actions and Uses.—Solution liver extract-Lilly is proposed for intramuscular injection in the treatment of pernicious anemia. See preceding article, Liver and Stomach Preparations.

Dosage.—In the average uncomplicated case of pernicious anemia in relapse a satisfactory response may be obtained with an initial dose of 5 to 20 U. S. P. units (injectable) daily for the first two or three days, after which weekly injections of 7 to 15 U. S. P. units (injectable) should be continued until the blood picture has returned to normal.

For maintenance of the average uncomplicated case after the normal picture has been established, a minimum of 1 U. S. P. unit (injectable) daily is usually sufficient and may be given as a cumulative dose. Patients exhibiting extensive neurologic involvement or other degenerative changes often require more than this average dose.

Manufactured by Eli Lilly & Co., Indianapolis. No U. S. patent or trademark.

Solution Liver Extract-Lilly, 2 U. S. P. Units per cc., 3.5 cc.: Marketed in rubber stoppered ampules for parenteral administration.

Solution Liver Extract-Lilly, 2 U. S. P. Units per cc., 10 cc.: Marketed in rubber stoppered ampules for parenteral administration.

Solution Liver Extract-Lilly, 1 U. S. P. Unit per cc., 10 cc.: Marketed in rubber stoppered ampules for parenteral administration.

Solution liver extract-Lilly is prepared from liver extract-Lilly. One batch of this powder is dissolved in water, the solution is filtered and 0.5 per cent phenol is added as a preservative. Another batch of the powder is treated with ammonium sulfate and alcohol to remove much of the total solids. This more highly potent material is then also made up in the form of a water solution, and 0.5 per cent phenol is added. The two different solutions thus obtained from separate batches of the powder are then mixed to obtain a solution with a potency of 2 U. S. P. injectable units per cubic centimeter. Products of lower potency are prepared by adding water to the final product.

SATURDAY, MAY 31, 1941

TRAUMA AND STRAIN IN RELATION TO POLIOMYELITIS

The widespread dissemination of the virus of poliomyelitis, when contrasted with the relatively limited incidence of the disease, suggests the existence of a number of contributing causative factors besides the virus. Isolated reports of the effects of either trauma or strain as predisposing factors in the development of acute anterior poliomyelitis are not infrequent. Frey¹ reported two cases following fractures in children 3 years old and one in a girl of 14 following the removal of a small chondroma from the left humerus. The disease developed within one month, two and one-half months and one and three-fourths months, respectively. The flaccid paralysis in each case corresponded to the seat of the trauma and to the same spinal cord segment. Zenke² reported three cases following trauma. The flaccid paralysis in her cases likewise involved muscle groups corresponding to the spinal cord segments originally involved in the trauma. Both authors believe that functional damage to the corresponding segment of the anterior horn ganglion cells acted as the predisposing factor. Bodily overexertion has recently been accorded particular attention as a possible predisposing cause. Thus, Voss³ reported the case of a girl aged 17 years who contracted acute anterior poliomyelitis of the Landry type after a strenuous tennis match. Bremer⁴ reported the case of a student in whom the disease developed following a difficult mountain climb. The observations of de Rudder and Petersen⁵ are particularly instructive in this connection. These authors describe two small epidemics which broke out abruptly after an athletic contest, in a boarding school located in a small rural community in southern Germany. The

boys were of the ages between 13 and 19, in the best of health and trained in athletics. Within a week after the athletic contest eleven boys came down with the disease. Another group of six boys came down with the disease following the second athletic contest a few days later. Three boys who attended the contest but did not participate in the games also developed the disease, bringing the total to twenty. Of these, 14 were abortive cases while 6 were complicated by paralyses. There were no other cases in that territory and none developed in the course of the following year. The total number of the boys in this school amounted to one hundred and seven; thus the morbidity was 20.5 per cent, which is much higher than any incidence thus far reported for any community.

Nase⁶ reported the case of a 26 year old soldier who, in the course of exercises, fell and struck his occiput and back. The accident was not followed by any alarming symptoms, so that the next day he was able to participate in a cross-country run, at the completion of which he appeared completely exhausted. There developed vomiting and rapid rise of temperature. On admission to the hospital the following morning he was not able to sit up in bed, to turn or to move his limbs except with difficulty. There was a moderate spasm of the right arm and some spasticity on bending the neck forward. His breathing was difficult. Death took place from respiratory paralysis nine hours after admission. The necropsy revealed no injury to the brain or the spinal cord. Microscopic examination revealed characteristic perivascular infiltration, lymphocytic and leukocytic infiltration, and destruction of the ganglionic cells of the anterior horns, most pronounced in the cervical segment of the spinal cord but also present in the medulla oblongata and in the white substance. The pathologist's diagnosis was acute anterior poliomyelitis. The presence of the patellar and abdominal reflexes, the spasticity of the right arm and the absence of flaccid paralyses constitute an atypical picture. However, Foerster and other writers have described atypical forms of acute anterior poliomyelitis in which increased reflexes and spasticity of certain muscle groups were associated with flaccid paralysis of some of the extremities. Such clinical pictures were seen in the fulminant cases and were the result of ascending degeneration of the pyramidal tracts. Wickmann, in his studies of the epidemics of 1911 to 1913 in Sweden, described four main clinical types: (1) the spinal, (2) the encephalitic, (3) the meningitic and (4) Landry's paralysis. Nase's case presents a combination of the encephalitic, the meningitic and the Landry type.

Recent experimental work throws additional light on the influence of chilling and overexertion on the development of poliomyelitis. Sabin⁷ has demonstrated that rhesus monkeys inoculated with the human virus may

develop a nonparalytic or even inapparent form of poliomyelitis with typical neuronal and infiltrative lesions in the spinal cord. He further found that the virus may actually reach the lower motor areas without paralysis necessarily ensuing, provided the proper equilibrium between the host and the virus exists or is achieved before too many nerve cells are affected. These observations have led to the consideration of assigning a new role to heavy exercise in the development of paralysis. The history of heavy exercise is frequently given by patients. Sabin found that the interval between this exercise and the onset of paralysis is usually less than twenty-four hours. This short interval, Sabin believes, suggests not only that those persons were already harboring the virus in their nervous system but also that it might already have involved their medulla and spinal cord and that the exercise could be the factor which converts what might have remained an unapparent or nonparalytic type of poliomyelitis into the frankly paralytic type of the disease.

Levinson⁸ demonstrated that monkeys immersed in cold water and compelled to swim to the point of exhaustion developed more severe paralysis than did either those which remained in their cages or those which were immersed in water at body temperature and protected from exercise and chilling.

The subject of body strain deserves particular attention in connection with military service.

THE SIGNIFICANCE OF MORTALITY STATISTICS

In a carefully documented discussion on mortality statistics, Van Buren¹ points out a number of deductions which cannot be proved by such data. Entirely too much importance and finality, he says, are attached to many crude death rates. Thus, if calculations from the crude death rates for cancer over the twenty-five year period 1911-1935 are made, one would conclude that the mortality rate had increased over 41 per cent in the last year of the time series as compared with the first year. When corrected, however, for the effect of the changing age distribution, it develops that the increase was only 14.5 per cent—an entirely different picture.

Another common mistake in interpretation of mortality figures is the utter disregard of the fact that data for the expanding death registration area do not relate to the entire country for years prior to 1933. An example of the dangers inherent in failure to recognize this fact is cited by Van Buren: A news bureau recently gave to the press a statement that deaths from a certain cause had increased in the United States from 8,959 in 1920 to 19,802 in 1938 and had therefore more than doubled. The 1920 figure, however, related to

only thirty-four states, the District of Columbia and sixteen cities in nonregistration states. The actual death rate was 10.2 per hundred thousand from this cause in 1920 and 15.2 in 1938. Obviously, the rate did not "more than double."

Similar difficulties in interpreting mortality statistics may be encountered merely because of change in classification under the International List of Causes of Death or may even be due to "fashion." Thus the rate for simple meningitis dropped continuously from 27.6 per hundred thousand in 1901 to 19.2 in 1905, while, at the same time, that for epidemic cerebrospinal meningitis rose from 5.7 to 15.0. The explanation, of course, is that there was constantly increasing care exercised by physicians to define "meningitis" as of the epidemic type. Similarly, the rate for diseases of the arteries almost doubled in these five years, owing largely to the growing practice of certifying "arteriosclerosis" instead of "old age," which latter, in turn, registered a continuously declining death rate.

Changing terms in the International List have resulted in many apparent alterations in the mortality data which do not, in fact, reflect the true picture. Thus, "endocarditis and myocarditis, unqualified, for ages 45 to 59" were transferred from the "acute endocarditis and myocarditis" title to the "other diseases of the heart" title. Since the proportion of the population in the 45 to 59 age group is steadily becoming larger, and since the terms endocarditis and myocarditis are often reported without qualification on the death certificates, these transfers assume considerable importance in their effect on the published death rates. Acute and chronic bronchitis can be cited as another title that presents difficulties with respect to comparability. The 1921 revision of the International List resulted in the transfer of the terms capillary bronchitis, cyst of bronchi and asthmatic catarrh from this rubric, while plastic bronchitis was added to it.

A classic example of misleading inferences from a time series of death rates is apparent in diseases of the coronary arteries. Death rates are available beginning with 1930, when deaths from coronary diseases were first segregated in the mortality statistics. If the figures are accepted at their face value, an astounding situation is revealed: one must conclude that in the short period of eight years the rate for this cause of death increased continuously from 8.0 per hundred thousand in 1930 to 52.0 in 1938. This abrupt rise is, of course, largely spurious. In the first place, diagnostic skill in relation to coronary diseases improved during the decade, but the chief factor in the apparent sharp increase was the growing "fashion" among physicians when clinical diagnosis was undertaken in cardiac cases to report the death as coronary occlusion, coronary thrombosis or coronary sclerosis. Thousands of deaths which prior to 1930 would have been allocated to other rubrics relating to diseases of the heart have been assigned, since 1930,

1. Van Buren, G. H.: Some Things You Can't Prove by Mortality Statistics.

to coronary disease. Factors such as Van Buren cites should lead toward the employment of extraordinary caution in the interpretation of comparative mortality statistics.

Current Comment

HYPOTHYROIDISM IN CHILDREN

Physicians often have difficulty in diagnosing hypothyroidism in children. One of the commonest errors is to think that mongolian idiots are cretins. Many times mongolian idiots referred by practicing physicians to children's clinics arrive with the diagnosis of cretinism. Mentally defective children are often considered to be cretins solely because of their retarded mental development and particularly if they happen to have a puzzled expression and queer physiognomy. Dwarfism, even if not accompanied by any of the stigmas of hypothyroidism, is often thought to depend on deficiency of the thyroid, probably because hypothyroidism is so well known as a cause of dwarfism. An error which has become common recently is to consider delay in the development of the centers of ossification of the epiphyses as being due to hypothyroidism. This is the outgrowth of the mistaken idea that the thyroid alone governs the maturation of the centers of ossification of the skeleton. The principal difficulty is that the physician is inclined to base the diagnosis of deficiency of thyroid on the finding of one or two suggestive signs. The paper of Wilkins and Fleischmann¹ which appears in this issue of THE JOURNAL is timely. It indicates the necessity of considering the entire clinical picture from the point of view of both functional and structural changes. Attention is drawn also to the fact that the character and extent of structural changes depend on the time of life when the deficiency occurs and the length of time it remains untreated.

THE BRAIN AND CHOLESTEROL METABOLISM

Comparatively recently it has been established that male and female sex hormones and the vitamin D group are cholesterol derivatives. The capacity of cholesterol esters to change into liquid crystalline anisotropic fats and to be deposited in the various tissues determines the unique character of disturbances of the cholesterol metabolism in pathology and particularly in the diseases of the aorta and arteries of man. P. D. Gorizontov,¹ working in the First Moscow Medical Institute, produced aseptic meningoencephalitis in dogs by subdural injection into the brain of either turpentine or silver nitrate. The comparative study of the blood cholesterol of the afferent arteries of the brain and of the blood cholesterol level of the efferent vessels of the brain demonstrated the development of hypercholesteremia in the experimental animals, which could not be explained on the basis of mobilization of choles-

terol from the lipid depots of the brain but which the author interprets as the result of the increase of cholesterol synthesis in the brain. Gorizontov correlated the various biochemical data obtained in his experiments with the morphologic alterations in the brain of his experimental animals and established the dependence of the blood cholesterol levels in his animals on the reactive processes on the part of the ectodermal neuroglia cells of the brain. This interesting and entirely new concept of the role of neuroglia in the cholesterol metabolism presents not only a theoretical but also a practical interest, since concepts in pathology thus far do not recognize humoral significance of the brain. In the light of the view advanced by the author, the role of neuroglia in cholesterol metabolism is that of a detoxifying process; toxic brain lesions themselves may be regarded as the result of disturbance of metabolic function of the neuroglia. Thus, hypercholesteremia as a result of hyperfunction of the neuroglia cells of ectodermal origin plays an important part in the lesions of internal organs, as for example in the development of atheromatosis of the aorta and of the arteries.

PROPHYLACTIC MEASURES FOR SYPHILIS AND GONORRHEA

The medical profession and the public health agencies bear a heavy responsibility for the prevention of syphilis and gonorrhea, especially during the present period of military mobilization. Both chemical and mechanical methods of prophylaxis have been definitely proved efficacious and, if their use is widely understood and correctly applied, there should be a great diminution in the incidence of both diseases. A preliminary statement on this subject by a special joint committee appointed by the American Social Hygiene Association and the United States Public Health Service, headed by H. H. Hazen, has recently appeared.¹ Health education with regard to syphilis and gonorrhea should include simple frank and explicit directions as to chemical and mechanical prophylaxis and in addition involves obligation on the part of health authorities to provide the facilities through which the means recommended may be made available. The following recommendations are made:

1. Safest method:
 - A. Use a condom of standard type.
 - B. Thoroughly wash the genitals and adjacent parts with soap and water as soon as possible (the sooner the better, but within one hour at most) after removal of the condom.
2. In the absence of a condom:
 - A. Thoroughly wash with soap and hot water as already described.
 - B. After urination, inject 6 cc. of 2 per cent strong protein silver solution, or other efficient, nonirritating germicidal solution into the urethra and hold for five minutes.
 - C. Rub 33 per cent ointment of mild mercurous chloride (calomel ointment) into the genitals and adjacent parts.

The committee emphasizes the fact that these methods are not 100 per cent successful but are sufficiently successful to deserve widespread application.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

NEUROPSYCHIATRIC EXAMINATION OF APPLICANTS FOR VOLUNTARY ENLISTMENT AND SELECTEES FOR INDUCTION

Circular Letter No. 19

1. The Surgeon General desires that medical officers examining applicants for voluntary enlistment and selectees for induction be especially alert to detect all persons with deficiency, constitutional psychopathy, prepsychotic and postpsychotic personality or psychosis and other persons who later may disrupt discipline and morale, retard progressive military training, occupy hospital beds urgently needed for acutely ill patients and finally become an economic burden on the government.

2. The following information is intended solely as a practical guide, and neuropsychiatrists are enjoined to apply it with discretion and mature judgment in order not to reject applicants or selectees without adequate and positive diagnostic indications of their unsuitability for active service, since their unwarranted rejection not only would constitute an injustice to the persons concerned but would deprive the government of their service.

3. During the period from April 1, 1917 to Dec. 31, 1919 no less than 97,657 patients were admitted to hospitals for persons with neuropsychiatric diseases. The major subclassification grouped 8,731 as hospitalized for epilepsy, 8,028 for neurasthenia, 4,310 for neurocirculatory asthenia, 6,090 for hysteria, 5,146 for constitutional psychopathic states, 13,063 for mental deficiency, 6,249 for dementia praecox, 7,501 for psychoneuroses, 5,652 for other types of psychoses and the remainder for various neuropsychiatric disorders. The foregoing brief analysis indicates the necessity of careful neuropsychiatric study of all questionable applicants on their examination at recruiting or induction stations.

4. The soldier must be looked on as a fighting unit requiring certain limited and definite qualifications. Not all persons are adaptable to restrictions and inhibitions of personal desires and comforts, to deprivation of rest, food or shelter or to the extraordinary demands for prolonged physical and mental activity often imposed by active military service. It must be remembered that many persons with abnormal personality traits who are capable of satisfactory adult adjustment in civilian life, in which numerous avenues of escape are available, will be at a total loss to adjust themselves to a pattern which is more or less inflexible and, of necessity, delimited and circumscribed as to self expression. When thrown on their own meager resources of adaptation in a military environment, in contact with all kinds of personalities, some who are just able to adapt themselves to life under the most favorable conditions will not fit into the one iron mold which experience has taught is essential to military success.

5. Applicants who manifest any of the following personality deviations require special attention on the part of the psychiatric examiner: instability, seclusiveness, sulkiness, sluggishness, discontent, lonesomeness, depression, shyness, suspicion, overboisterousness, timidity, sleeplessness, lack of initiative and ambition, personal uncleanness, stupidity, dullness, resentfulness to discipline, nocturnal incontinence, sleepwalking, recognized queerness, suicidal tendencies (bona fide or not) and homosexual proclivities.

6. A brief résumé of the more common neuropsychopathic conditions is as follows:

GROUP I. *Mental Defects and Deficiencies.*—These are manifested by a lack of general information concerning the native environment; inability to learn, to reason, to calculate, to plan, to construct, to compare weights, and so on; defect in judgment, foresight, language and output of effort; suggestibility; untidiness; lack of personal cleanliness; anatomic stigmas of degeneration, and muscular awkwardness. The history of the school life and the vocational career as well as the disciplinary report will assist materially; then the applicant should be classified according to psychometric standards.

Examiners should use extreme care and judgment in reporting their findings on the enlistment record, since these records are given to the registrants when they are rejected and become common knowledge in the community. Such terms as "imbecile" and "moron" will not be used, but an approximate psychometric scaling will be listed as the cause for rejection, such as "mental age, 8 years." Elaborate psychometric estimation is not necessary, and any accepted abbreviated method will suffice. Intelligence cannot be definitely estimated, and no infallible test is available. The results are all only approximations and must be evaluated only in conjunction with accompanying factors and circumstances.

Illiteracy per se is not to be classified as mental deficiency.

GROUP II. *Psychopathic Personality Disorders.*—Under this heading is placed an ill defined, more or less heterogeneous group of conditions in which the patients, although they do not suffer from a congenital defect in the intellectual sphere, manifest a definite defect in their ability to profit by experience. They are unable to proceed through life with any definite pattern of standardized activity. They are unable to respond in an adult social manner to the demands of honesty, truthfulness, decency and consideration of their associates. They are emotionally unstable and not to be depended on; they act impulsively, with poor judgment; they are always in difficulties, have many and various schemes without any logical basis, lack tenacity of purpose, are easily influenced and are often in conflict with the law. They do not take kindly to regimentation and are continually at variance with those who attempt to indoctrinate them in the essentials of military discipline. Such persons have a decided influence on their associates and on the morale of the organization, for they will not conform to organized authority, and they derive much satisfaction from cultivating insubordination in others. Frequently they make a favorable impression, are neat, talk well and are well mannered. However, under this veneer the real defect is evident by past irresponsiveness to social demands and lack of continuity of purpose. In this general group are to be placed many homosexual persons, grotesque and pathologic liars, vagabonds, inadequate and emotionally unstable persons, petty offenders, swindlers, kleptomaniacs, pyromaniacs, alcoholic persons and likewise those highly irritable and arrogant persons the so-called pseudoquerulents ("guardhouse lawyers"), who are forever critical of organized authority and imbued with feelings of abuse and lack of consideration by their fellows.

GROUP III. Major Abnormalities of Mood.—Major abnormalities of mood are shown by episodes of unreasonable elation or depression which tend to recur without obvious connection with events. Persons who are known to be so mercurial in their reactions that their judgment is seriously impaired during the upward or downward swing of their moods should be rejected. Registrants known to have received medical or nursing care because of morbid excitement or depression should be rejected.

GROUP IV. Psychoneurotic Disorders.—Psychoneurotic disorders present a more difficult diagnostic problem. The signs and symptoms fall more or less clearly into one of three major categories: the hysterical, physical signs and symptoms often so dramatic that they may seem fraudulent and do not follow anatomically understandable patterns; the morbidly anxious, various signs and symptoms of fear, and the obsessional, which include such varied conditions as hypochondriacal states (pre-occupation with one's ill health); morbid fears (phobias), and rituals of action and thought which the patients feel compelled to carry out.

The examiner should look for hysterical stigmas, such as cutaneous anesthesia (especially hemianesthesia); contractions of the visual fields, and so on; phobias; morbid doubts and fears; attacks of anxiety; compulsions, and hypochondriasis. He should compare the complaints with the behavior and obtain a history as to former nervous breakdowns and vocational career.

For purposes of classification, there are to be placed in this group the so-called psychosomatic disorders, mental or personality difficulties chiefly characterized by signs and symptoms of systemic disease—respiratory, gastrointestinal, cardiac, genitourinary or cutaneous. These include many examples of asthma, urticaria, "neurasthenic states," neurocirculatory asthenia, "effort syndrome," disordered action of the heart, paroxysmal tachycardia, gastric hyperacidity, pylorospasm, gastric and duodenal ulceration, spastic constipation and diarrhea, mucous colitis, impotence, urinary urgency or frequency and incontinence of semen. The examiner should look for a clear relation in the history of attacks coinciding with periods of personal stress and of improvement with separations from the accustomed stressful surroundings. These conditions sometimes appear early in the course of prepsychotic states discussed under group V.

GROUP V. Conditions Associated with Dementia Praecox.—This category comprises grave mental or personality handicaps. Persons with prepsychotic or postpsychotic personality and persons actually suffering from a schizophrenic ("dementia praecox") mental disorder manifest their condition by obscurely motivated peculiarities of behavior and thought. Of these, the so-called deteriorated states are the most obvious. Among such persons belong the numerous shiftless, untidy, perhaps morose, sometimes nomadic persons who have had what was regarded as a normal childhood. Somewhere between the ages of 12 and 25 they underwent a change, acute or insidious, with dilapidation of their social interests and the habits in which they had been trained. They may or may not have received treatment in hospitals for mental diseases.

Paranoiac personality traits comprise another large division. Paranoid persons cling to fantastic beliefs in their overwhelming importance and often feel that others are persecuting them or otherwise interfering with their career or their well being. Some of them believe that they are in communion with supernatural beings. Others believe that they are victims of plots, secret organizations, spy rings or religious or fraternal groups. They are often plausible in supporting these delusions by clever misinterpretation of facts. Some of them are evasive and skilful at concealing their disorder. A morbid suspiciousness of any one who takes an interest in them is frequent. They may become tense and hateful when interrogated. An attitude of unusual cautiousness or suspiciousness toward the examining physician or toward fellow registrants should suggest the possibility of paranoia.

The catatonic and prepsychotic states may present great difficulty in diagnosis. Perhaps the only obvious sign of these

conditions is the impression of queerness. The actual oddities of behavior or thought may be subtle; it may be difficult in retrospect to point to any particular instances of the unusual. The most striking signs of these conditions may, in fact, come out in connection with the physical examination. The physician at some stage of the physical examination may observe a peculiar reaction which on questioning may awaken a suspicion of a prepsychotic state. Prepsychotic persons frequently entertain unfounded convictions as to bodily peculiarities or disorders which they attribute to excessive sexual acts of one sort or another. These beliefs, sometimes hard to elicit, are often medically incredible and bizarre. Questioning such persons on intimate personal matters often leads to great embarrassment, confused speech or actual blocking of thought, so that they do not know what to say.

Salient Deviations: These are indifference; apathy; withdrawal from the environment; ideas of reference and persecution; feelings of the mind being tampered with or of the thoughts being controlled by hypnotic, spiritualistic or other mysterious agencies; hallucinations of hearing; bodily hallucinations, frequently electrical or sexual; meaningless smiles, and, in general, inappropriate emotional reactions and a lack of connectedness in conversation. There may be sudden emotional or motor outbursts. The examiner should get the history of the family life and of the school, vocational and personal career.

GROUP VI. Conditions Due to Chronic Inebriety.—As evidences of alcoholism, one should look for suffused eyes; prominent superficial blood vessels of the nose and cheek; a flabby, bloated face; red or pale purplish discoloration of the mucous membrane of the pharynx and the soft palate; muscular tremor in the protruded tongue and extended fingers; tremulous handwriting; emotionalism; prevarication; suspicion; auditory or visual hallucination, and persecutory ideas. Early inebriety, especially in young selectees with morbid addiction to alcohol, may show no objective signs. A verified history of frequent breach of the law when drunk or of hospital treatment on account of alcoholism should be regarded as disqualifying.

For drug addiction one should look for pallor and dryness of the skin. If the drug is being used, the attitude is that of flippancy and mild exhilaration; if the drug has been withdrawn, it is cowardly and cringing. During the period of withdrawal there are also restlessness, anxiety and complaints of weakness, nausea and pains in the stomach, back and legs. There is distortion of the alae nasi. The pupils are contracted by morphine and dilated by cocaine. All habitual drug takers are liars. They do not drink, as a rule, and are inactive sexually. Many drug takers use needles and show white scars on the thighs, arms and trunk. Diacetylmorphine (heroin) addicts are mostly young men from the cities, often gangsters. They have a characteristic vocabulary and will talk much more freely about the habit if the examiner in his inquiries uses such words as "deck," "quill," "package," "an eighth," "blowers" and "cokie." A verified history of arrest for violation of the narcotic law should be regarded as disqualifying.

GROUP VII. Conditions Accompanying Syphilis of the Central Nervous System.—One should look for anomalous reaction of the pupil, facial tremor, speech defect in test phrases and in slurring and distortion of words in conversations and writing defects consisting of omissions and distortions of words. The mood is apathetic, depressed or euphoric. There are loss of memory and discrepancies in relating the facts of life. The knee jerks may be plus, minus or normal.

GROUP VIII. Other Organic Diseases of Brain, Spinal Cord or Peripheral Nerves.—Certain after-effects of organic nervous disease need not be causes for rejection provided (1) the disease is no longer operative and is not likely to recur and (2) the effect left by it does not prevent a satisfactory fulfillment of military duties. Examples of such conditions are paralysis of a few unimportant muscles following poliomyelitis; slight unilateral hypertonicity resulting from infantile hemiplegia in a man now robust, and various traumatic conditions. A history of hemiplegia occurring after infancy should always disqualify, even if no symptoms remain.

Existent organic nervous disease should always disqualify for military service. For example, neuritis of one or many nerves, while capable of recovery without resultant defect, is none the less a cause for rejection as long as it exists. The following organic nervous diseases are mentioned specifically, as they are the ones which frequently present few symptoms and may pass undetected by even the most skilful examiners:

Multiple Sclerosis: The symptoms are intention tremor, nystagmus, absence of abdominal reflexes and increased tendon reflexes. The scanning speech may be mistaken for stammering. There is no history of pain, but sometimes there is a history of urinary disturbance.

Progressive Muscular Atrophies and Dystrophies and Syringomyelia: One should look for atrophies in the small muscles of the hand and in the muscles of the shoulder girdle, with fibrillary twitchings. These plus anesthesia for heat and cold (scars on the hands from cuts and burnings) suggest syringomyelia. The history usually furnishes few data, although reference may be made to awkwardness. There is no history of pain. Syphilitic spinal disease imitates these conditions closely.

Epilepsies: There may be deep scars on the tongue, face and head. The voice is frequently characteristic. If one has the history alone, which may include incidents called faintness, dizziness or spasms of the face or of an extremity, one should verify by correspondence with physicians if practicable.

Hyperthyroidism: This is a nervous disease in its effects. There are persistent tachycardia, exophthalmos, tremor and an enlarged thyroid. There is a history of general nervousness.

7. In addition to the foregoing conditions, there are certain groups of symptoms which should be carefully investigated. They may not by themselves be sufficient for an exact diagnosis, but they generally indicate that the nervous system is seriously diseased and totally undependable for any continuous service.

General Symptoms.—These include abnormal attitudes, postures, contractions, contractures, deformities, atrophies or hypertrophies, marked kyphosis, scoliosis or lordosis, vasomotor or trophic disturbances, abnormal bodily and facial distribution of hair and abnormal distribution of fat.

Station and Gait.—A spastic gait, a scissors gait, marche à petits pas, cerebellar ataxia, a grotesque, histrionic or dancing

gait, steppage, waddling, a bizarre gait, a nondescript gait (as seen in hysterical conditions), festination, propulsion, retropulsion, lateropulsion or loss or diminution of the normal automatic associated finer movements in walking may be observed.

Abnormal Coordination.—This is shown by the Romberg sign, cerebral and cerebellar ataxia, nonequilibrium ataxia, dysmetria and adiadosokinesis.

Abnormal Motility.—There may be abnormal motility of the eyes, face, mouth, neck or large joints.

Abnormal Involuntary or Spontaneous Movements.—Tremors, intentional or otherwise, nystagmus, fibrillation, choreic movements, athetosis or spasm may be noted.

Abnormal Reflexes.—Various reflex abnormalities may be present throughout the body (Babinski, Oppenheim, Gordon or Chaddock sign; grasping and groping reflexes; ankle clonus).

Sensory Abnormalities.—There may be hypesthesia, hyperesthesia, paresthesia, analgesia, thermesthesia, altered vibratory, joint, tendon or position sense, defective localization or defective stereognosis.

Evidence of Pathologic Change in Cranial Nerves.—This includes areas of tenderness over the calvarium and postencephalitic and posttraumatic syndromes.

8. The Army is one of the elements of national defense, and its present mission is one of preparation for an offensive-defensive type of warfare. It is in no sense a social service or a curative agency. It is to be considered neither a haven of rest for wanderers nor a corrective school for misfits, ne'er-do-wells, feeble-minded persons or chronic offenders. Furthermore, it is neither a gymnasium for the training and development of the undernourished or undeveloped nor a psychiatric clinic for proper adjustment to adult emotional development. Therefore, there is no place within the Army for physical or mental weaklings, potentially psychotic or prepsychotic persons or behavior problems. Men who present behavior problems in the civilian community will certainly present intensified problems in the service.

9. While the aforementioned facts are brought to the examiner's attention, he is enjoined to interpret them not as a basis for lightly rejecting men for military service but rather as points on which to evaluate them with a view to eliminating the unfit and retaining those capable of satisfactorily performing the duties of soldiers.

THE NATIONAL YOUTH ADMINISTRATION HEALTH PROGRAM

While about 80 per cent of the young people employed by the National Youth Administration are fit for any type of work, nine out of every ten have health defects, most of which can be remedied provided suitable treatment is made available, according to preliminary statistics compiled under the health program of the National Youth Administration.

These figures are based on the results of medical examinations of ten thousand NYA workers made by local practicing doctors and dentists who have been employed by the National Youth Administration to do this work. The records tabulated to date reflect the health needs of youth as seen by physicians from twenty-one states representing all geographic regions of the United States.

With the cooperation of the medical profession as well as of federal and state health authorities, the National Youth Administration's health program now operates in all states. The basis of this health program, which is an important part of the defense work of this agency, is a medical examination which facilitates assignment of youth to suitable work activities and at the same time discloses to young people their need for remedial treatment.

While the primary aim of the NYA is to provide young people with basic work experience to fit them for jobs in private industry, it has a logical concern with building up the health

and physical fitness of its employees, both from the standpoint of the national welfare and as the largest employer of youth labor in the country.

HEALTH STATUS CLASSIFICATION

Young people who have been given health examinations have been grouped into health status classifications according to their physical ability to work and to engage in athletic activity. While six groupings are actually being used, these will be condensed here into four:

Group A comprises 78 per cent of all youth examined. It represents those who are at present fit for any type of employment or athletic activity. The individuals of this group, although fit for any employment, received one hundred and thirty health recommendations for each hundred youths. The rate for females was considerably higher than for males.

Group B comprises 13 per cent of all youth examined. It represents those who have defects not thought to be amenable to correction but not severely handicapping. There were one hundred and sixty health recommendations for each hundred youths in this group.

Group C comprises 5.5 per cent of all youth examined. It represents those whose assignment to a particular job should be approved by a physician. Some require medical supervision on the job. There were two hundred and ten health recommendations for each hundred youths in group C.

1. The National Youth Administration Contributes to the National Health, J. A. M. A. 115:2185 (Dec. 21) 1940.

Group D comprises 2.5 per cent of those examined. It represents those who are temporarily or permanently unfit for any employment. There were two hundred and ninety health recommendations for each hundred youths.

RECOMMENDATIONS, TYPE AND AMOUNT

Dental care was recommended for 56 per cent of those examined. This is made up of recommendations made by both physicians and dentists. If dentists had been used to make the dental examination for each youth, the figure would have been considerably higher, since among youth examined by dentists 72 per cent were reported as having carious teeth, while physicians reported only 47 per cent.

It is of interest that, in 10 per cent of the youth, each had from ten to thirty decayed teeth.

Tonsillectomy was recommended for 15 per cent.

Refraction was recommended for 15 per cent.

Special diets were recommended for 10 per cent.

Minor surgery, including hemorrhoidectomies and circumcisions, was recommended for 6 per cent.

Veneral disease treatment was recommended for 2 per cent. If a youth is already under treatment for a venereal disease, many physicians do not recommend treatment in this type of examination, although they do note presence of the disease.

Major surgery, including hernia repair, was recommended for 2 per cent.

Hookworm treatment was recommended for 2 per cent. Considering youth from the Southern states only, treatment for hookworm disease and hookworm infection was recommended for 5 per cent.

OTHER FINDINGS

Slightly over 5 per cent were described as being malnourished, while obesity was present in 3 per cent.

Organic heart disease was reported in almost 3 per cent of those examined.

In this first group to be reported, tuberculin testing and chest roentgenograms had not been completed; however, the finding

of 95 cases of pulmonary tuberculosis were reported, of which 26 were active.

One of the most significant results of these examinations as far as the medical profession is concerned is the revelation that 25 per cent of the youths examined reported they had never been to a dentist and 18 per cent reported that they had never been to a physician. This disclosure is especially meaningful when one remembers that this is a group of young people who have been out of our public schools only a short time and presents a real challenge to those interested in health education and the application of preventive medicine.

The eight leading health defects for which corrections have been recommended can largely be taken care of in clinics or offices of physicians and dentists. Only a small group need hospitalization. Most of the health defects noted do not affect, at this early age, the ability of approximately 80 per cent of these youths to work, but many of the defects will influence unfavorably the selection of many youths by private industry and will, at a slightly later stage in life, decidedly affect the efficiency of the individual on any job, as well as eligibility for military service.

One of the main contributions of the NYA in obtaining treatment for young people who need it has been the payment of a wage to its youth employees which has enabled many to pay the cost of medical and dental care. NYA has placed many young people in contact with practicing physicians and dentists and has encouraged special private arrangements between the youth and the physician for defraying the cost of professional services. Where public or private clinics exist, it has been possible to facilitate access to these agencies for a sizable group of young people.

On the basis of experience thus far, it is believed that about 50 per cent of the NYA youth can be provided with needed health service through some such arrangements, depending on geographic locations. The remaining group of youth present a problem for which there is no present solution.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY WAR DEPARTMENT

The following additional medical reserve corps officers have been ordered to extended active duty by the War Department, Washington, D. C.:

ANDERSON, Milford Xerxes, 1st Lieut., Los Angeles.
ARNESON, Charles Albert, Captain, Fargo, N. D.
AXELROD, Harold, 1st Lieut., Brooklyn.
BAKER, Norman Ludlow, 1st Lieut., Chicago.
BALL, George Lindsay, Captain, Washington, D. C.
BARRETT, Richard Henry, 1st Lieut., Rochester, Minn.
BARTLETT, Walter Merritt, 1st Lieut., Benton Harbor, Mich.
BEERNINK, Ernest Henry, Captain, Grand Haven, Mich.
BERMAN, Leonard Stanley, 1st Lieut., Washington, D. C.
BISHOP, Harold Francis, 1st Lieut., Valhalla, N. Y.
BOSS, Myron Theodore, 1st Lieut., Baltimore.
BROWN, Charles Howard, 1st Lieut., Beverly Hills, Calif.
BURFORD, Edgar Humber, Captain, St. Louis.
BURRAGE, William Champlin, 1st Lieut., Boston.
CHALLMAN, Samuel Alan, Captain, Minneapolis.
DAVIS, Fenimore Edison, Captain, Ann Arbor, Mich.
DELEHANTY, John Thomas, 1st Lieut., Lattimer, Luzerne County, Pa.
FIENBERG, Robert A., 1st Lieut., Westfield, Mass.
FISHER, Roy Lee, Captain, Frederick, Okla.
FRENCH, Adam James, 1st Lieut., Ann Arbor, Mich.
GOLDBERG, Solomon, Captain, Pittsburgh.
HARWELL, Carl Mallory, Jr., 1st Lieut., Memphis, Tenn.

FIRST CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, First Corps Area, which comprises the states of Maine, Vermont, New Hampshire, Massachusetts, Rhode Island and Connecticut:

ALLEN, Howard H., 1st Lieut., Greensboro, Vt., Fort Devens, Mass.
ANDERSON, Donald L., 1st Lieut., Caribou, Maine, Fort Devens, Mass.
ANDERSON, Fred A., 1st Lieut., West Roxbury, Mass., Fort Devens, Mass.
ANTOS, Chester J., 1st Lieut., Salem, Mass., Fort Devens, Mass.
ARCHAMBAULT, Rene F., Captain, Barre, Vt., Fort Devens, Mass.
BARD, Henry H., Captain, Pittsfield, Mass., Camp Edwards, Mass.
BARRETT, Charles G., Captain, Amherst, Mass., Fort Devens, Mass.

ISLER, Nathaniel Charles, Captain, Jeffersonville, Ind.
KING, Albert Terrence, 1st Lieut., Salem, Ore.
KREFT, Alfred John, 1st Lieut., Des Plaines, Ill.
KROTCHER, Lester Clayton, Captain, Twin Falls, Idaho.
LEA, Joseph Davis, 1st Lieut., New Orleans.
LEFFINGWELL, Forrest Emmett, Captain, Montebello, Calif.
McLOUGHLIN, Christopher John, 1st Lieut., Rochester, Minn.
MALTRY, Emile, Jr., 1st Lieut., New Orleans.
MILLER, Samuel Lewis, Captain, Cheboygan, Mich.
NACHTMAN, Howard Frank, 1st Lieut., Portland, Ore.
NEIBRIEF, Milton Nelson, 1st Lieut., Brooklyn.
NOONAN, Thomas Robert, 1st Lieut., Rochester, N. Y.
PLUM, John Bernard, 1st Lieut., Grand Rapids, Mich.
POWERS, Pierce William, 1st Lieut., St. Louis.
REEVES, David Lander, Captain, Los Angeles.
RICE, Dale Arthur, 1st Lieut., Meadville, Pa.
SEID, Sidney E., Captain, Chillicothe, Okla.
SMITH, Eugene, 1st Lieut., Waterloo, Iowa.
SPENCER, Newton Carman, Major, Toledo, Ohio.
STADLER, Harold Erwin, 1st Lieut., Iowa City.
SUGAR, Samuel Jacob Nathan, 1st Lieut., Washington, D. C.
TANNER, Henry Seiver, 1st Lieut., Indianapolis.
THATCHER, Donald Sheldon, 1st Lieut., Milwaukee.
WHITEHEAD, Duncan, Captain, Leominster, Mass.
WOLPAW, Sidney Elmer, 1st Lieut., Cleveland Heights, Ohio.
YOUNG, John D., Jr., 1st Lieut., Lexington, Ky.

BOTTAMINI, Joseph T., 1st Lieut., Burlington, Vt., Fort Devens, Mass.
BROWE, John H., 1st Lieut., Hartford, Conn., Fort Williams, Maine.
BURGIN, Leo B., Captain, Brookline, Mass., Fort Devens, Mass.
BUTTLES, Roy V., 1st Lieut., Burlington, Vt., Fort Devens, Mass.
CAHILL, Francis P., 1st Lieut., Cambridge, Mass., Manchester, N. H.
CAMPBELL, Kenneth D., 1st Lieut., Somerville, Mass., Manchester, N. H.
CASE, Edward P., Lieut. Col., West Hartford, Conn., Fort Adams, R. I.
CHOATE, Paul M., 1st Lieut., West Barnet, Vt., Fort Devens, Mass.
CLARK, Benjamin F., Captain, St. Johnsbury, Vt., Fort Devens, Mass.
CLEMENT, Howard R., 1st Lieut., Boston, Camp Edwards, Mass.
CURTIS, Sprague, 1st Lieut., Westfield, Mass., Fort Devens, Mass.
DENNING, Walter S., 1st Lieut., Brookline, Mass., Fort Devens, Mass.
DeWITT, Reginald F., 1st Lieut., Plymouth, N. H., Fort Devens, Mass.
EASTMAN, Cyrus D., 1st Lieut., Monroe, N. H., Fort Devens, Mass.

ESTABROOK, John S., 1st Lieut., Brandon, Vt., Fort Devens, Mass.
FINKS, Henry, 1st Lieut., Portland, Maine, Bangor, Maine.
FROMER, John L., Captain, Brookline, Mass., Fort Devens, Mass.
GALLERY, Daniel F., 1st Lieut., Fall River, Mass., Manchester, N. H.
GENCARELLI, Alphonse F., 1st Lieut., Hartford, Conn., Fort Devens, Mass.
GINGOLD, Thomas L., Major, New Haven, Conn., Fort Banks, Mass.
GLADSTONE, Arthur, 1st Lieut., Burlington, Vt., Bangor, Maine.
GODDARD, Philip A., 1st Lieut., Morrisville, Vt., Bangor, Maine.
GOERGE, William P., 1st Lieut., Danbury, Conn., Bangor, Maine.
GOLDSBERRY, John J., 1st Lieut., Worcester, Mass., Fort Dix, N. J.
GOODRICH, William, 1st Lieut., Bridgeport, Conn., Fort Devens, Mass.
HAMMER, Joseph, 1st Lieut., Wellesley, Mass., Bangor, Maine.
HARWOOD, Clarence W., 1st Lieut., Burlington, Vt., Fort Devens, Mass.
HARWOOD, Clifford B., 1st Lieut., Whitingham, Vt., Fort Devens, Mass.
HERSEY, Thomas F., 1st Lieut., Hamden, Conn., Fort Devens, Mass.
HOBBS, Milford L., 1st Lieut., Burlington, Vt., Camp Edwards, Mass.
ISENSTEIN, Charles, 1st Lieut., Dorchester, Mass., Camp Edwards, Mass.
JORESS, Mark H., 1st Lieut., Lynn, Mass., Camp Edwards, Mass.
LAKE, Fredric D., 1st Lieut., Springfield, Mass., Fort Devens, Mass.
LEVIN, Harold M., 1st Lieut., Burlington, Vt., Bangor, Maine.

FOURTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Fourth Corps Area, which comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana:

ANTONAKOS, Theodore, 1st Lieut., Winston-Salem, N. C., MacDill Field, Fla.
ASLING, Clarence W., 1st Lieut., Nashville, Tenn., Camp Croft, S. C.
AUERBACH, Stewart H., Captain, Augusta, Ga., Camp Wheeler, Ga.
BAILEY, Thomas E., 1st Lieut., Augusta, Ga., Camp Davis, N. C.
BANNIS, John Adam, 1st Lieut., Birmingham, Ala., Fort Bragg, N. C.
BARKOFF, Samuel A., 1st Lieut., New Orleans, MacDill Field, Fla.
BASS, Beatty Lee, 1st Lieut., Winston-Salem, N. C., Fort Bragg, N. C.
BLACK, Charles L., 1st Lieut., Couthatta, La., Camp Polk, La.
BLEECKER, Philip B., 1st Lieut., Memphis, Tenn., Fort Bragg, N. C.
BODDIE, James B., Jr., 1st Lieut., Nashville, Tenn., Fort Benning, Ga.
BOMBET, Charles N., 1st Lieut., Baton Rouge, La., Fort Benning, Ga.
BOSTWICK, Jackson L., 1st Lieut., Jacksonville, Fla., Fort Benning, Ga.
BOURKARD, Ernest Richard, 1st Lieut., Miami, Fla., Camp Davis, N. C.
BOWEN, Jack H., 1st Lieut., Jacksonville, Fla., Fort Bragg, N. C.
BRANNEN, Frank S., 1st Lieut., Chattanooga, Tenn., Fort Bragg, N. C.
BYRON, Robin Adair, 1st Lieut., New Orleans, Fort Bragg, N. C.
CASH, Ralph Louard, 1st Lieut., New Orleans, Fort Bragg, N. C.
CHAMBERS, John M., Jr., 1st Lieut., Memphis, Tenn., MacDill Field, Fla.
COOLEY, Beamon S., Jr., 1st Lieut., Birmingham, Ala., Fort Barrancas, Fla.
CROFT, Theodore C., 1st Lieut., Jacksonville, Fla., Camp Livingston, La.
DANIEL, Rollin A., Jr., Captain, Nashville, Tenn., Camp Forrest, Tenn.
DODSON, George D., Jr., 1st Lieut., Chattanooga, Tenn., Camp Croft, S. C.
DOWELL, James W., 1st Lieut., Pineville, La., Camp Croft, S. C.
DOZIER, Horace B., 1st Lieut., New Orleans, Camp Croft, S. C.
DURHAM, Bon M., 1st Lieut., Augusta, Ga., Camp Croft, S. C.
DYER, John Lewis, 1st Lieut., New Orleans, Camp Blanding, Fla.
ELLIOTT, Cecil B., 1st Lieut., Gainesville, Ga., Fort Bragg, N. C.
ELLIS, Frank F., Jr., 1st Lieut., Birmingham, Ala., Fort Bragg, N. C.
FARRAGUT, Loyall David, Captain, Jonesboro, Tenn., Camp Forrest, Tenn.
FARRAR, Taylor, 1st Lieut., Shelbyville, Tenn., Camp Forrest, Tenn.
FISHER, William G., 1st Lieut., New Orleans, Fort Bragg, N. C.
FITZGERALD, William J., 1st Lieut., New Orleans, Camp Davis, N. C.
FUNK, Barclay, 1st Lieut., Alexandria, La., Camp Polk, La.
GRAY, Cyrus L., Jr., 1st Lieut., Durham, N. C., Camp Claiborne, La.
GREEN, Arthur W., 1st Lieut., Memphis, Tenn., Fort Bragg, N. C.
GREEN, Daniel M., 1st Lieut., Memphis, Tenn., Camp Blanding, Fla.
GREEN, James A., 1st Lieut., Atlanta, Ga., MacDill Field, Fla.
GREENBERG, S. A., 1st Lieut., Florence, S. C., Camp Polk, La.
GRIMES, William H., Jr., 1st Lieut., Colquitt, Ga., Fort Bragg, N. C.
HARRIS, Reuben Rhys, 1st Lieut., Birmingham, Ala., Camp Blanding, Fla.
HARVARD, Bell M., Jr., 1st Lieut., New Orleans, Fort Benning, Ga.
HASPEL, Robert B., 1st Lieut., New Orleans, Fort Benning, Ga.
HENDERSON, Hillary H., Jr., 1st Lieut., Birmingham, Ala., Camp Livingston, La.
HENRY, Blonely S., 1st Lieut., Memphis, Tenn., Camp Davis, N. C.
HERBERT, William C., Jr., 1st Lieut., Spartanburg, S. C., Camp Forrest, Tenn.
HICKS, David Y., Jr., 1st Lieut., Augusta, Ga., Camp Wheeler, Ga.
HILL, Thurman K., 1st Lieut., Nashville, Tenn., Camp Livingston, La.
HILLARD, Irving R., 1st Lieut., Jackson, Tenn., Fort Bragg, N. C.
HOLLIMAN, Henry D., Jr., 1st Lieut., Atlanta, Ga., Fort Jackson, S. C.
HOLLOMAN, Walter G., 1st Lieut., Monroe, La., Camp Wheeler, Ga.
HOLMES, Verner S., 1st Lieut., McComb, Miss., Camp Forrest, Tenn.
HOLT, Benton B., Jr., 1st Lieut., Charleston, S. C., Fort Jackson, S. C.
HORN, Philip Webster, 1st Lieut., New Orleans, Camp Blanding, Fla.
HUBBARD, George B., 1st Lieut., Nashville, Tenn., Camp Forrest, Tenn.
HUTTON, Vernon, Jr., 1st Lieut., Nashville, Tenn., Fort Jackson, S. C.
JACKSON, Truxton L., 1st Lieut., Nashville, Tenn., Fort Bragg, N. C.
JEANES, James Gregg, 1st Lieut., Clinton, S. C., Camp Davis, N. C.
JERNIGAN, Sterling H., 1st Lieut., Atlanta, Ga., Fort Benning, Ga.
LEVIN, Spencer E., Captain, Roxbury, Mass., Fort Devens, Mass.
LEVINE, David I., 1st Lieut., Weymouth, Mass., Camp Edwards, Mass.
MAHONEY, James P., 1st Lieut., Burlington, Vt., Fort Devens, Mass.
MELLION, Jacob, Captain, New Britain, Conn., Camp Edwards, Mass.
MERRIAM, Philip G., 1st Lieut., New Britain, Conn., Fort Devens, Mass.
MILLSTEIN, Hyman, 1st Lieut., Southwest Harbor, Maine, Fort Devens, Mass.
MONROE, Willys M., Major, Pittsfield, Mass., Camp Edwards, Mass.
MONTGOMERY, Eugene P., 1st Lieut., Boston, Camp Langdon, N. H.
PERLEY, John R., 1st Lieut., Lakeport, N. H., Fort Devens, Mass.
RABNOWITZ, Henry, 1st Lieut., Brockton, Mass., Camp Edwards, Mass.
RADCLIFFE, Ernest J., Captain, Amherst, Mass., Bangor, Maine.
SKELTON, Alton B., 1st Lieut., Winchendon, Mass., Camp Edwards, Mass.
SMITH, Joseph, Captain, Providence, R. I., Manchester, N. H.
TIMMERMAN, Frederick W., 1st Lieut., Morrisville, Vt., Fort Devens, Mass.
TUCKER, Arthur S., 1st Lieut., New Haven, Conn., Camp Edwards, Mass.
TUOHY, Edward L., 1st Lieut., Cambridge, Mass., Camp Edwards, Mass.
TWADELLE, Frank J., 1st Lieut., Wellesley, Mass., Camp Edwards, Mass.
KALMON, Edmond H., Jr., 1st Lieut., Nashville, Tenn., Camp Davis, N. C.
KELLY, Alex R., Jr., 1st Lieut., Augusta, Ga., Camp Davis, N. C.
KUNTZ, William M., 1st Lieut., New Orleans, Camp Claiborne, La.
LAMBETH, Samuel S., III, 1st Lieut., Durham, N. C., Fort Bragg, N. C.
LANE, Thomas H., 1st Lieut., Fairfield, Ala., Camp Livingston, La.
LEVIN, Harold B., 1st Lieut., Atlanta, Ga., Camp Blanding, Fla.
LEWIS, Lawrence C., Jr., 1st Lieut., Tuskegee, Ala., Camp Blanding, Fla.
LOVE, William G., Jr., 1st Lieut., Atlanta, Ga., Fort Benning, Ga.
LOWENSTEIN, Sol L., 1st Lieut., Nashville, Tenn., Camp Livingston, La.
LYLE, Philip Lewis, 1st Lieut., Clarksville, Tenn., Camp Polk, La.
MACPHERSON, Ford J. A., 1st Lieut., Iberlin, La., Camp Shelby, Miss.
MCCOOK, Walter W., Jr., 1st Lieut., Shreveport, La., Fort Bragg, N. C.
MAGNE, Jacques A., 1st Lieut., New Orleans, Camp Polk, La.
MARTIN, George H., 1st Lieut., Anguilla, Miss., MacDill Field, Fla.
MASON, James M., III, 1st Lieut., Birmingham, Ala., Fort Bragg, N. C.
MASTERS, ELIAS W., 1st Lieut., Anderson, S. C., Fort Jackson, S. C.
MICKAL, Abe, 1st Lieut., New Orleans, Fort Bragg, N. C.
MILLER, John M., 1st Lieut., Augusta, Ga., Fort Bragg, N. C.
MITCHELL, Charles B., Major, Mississippi A. & M. College, Camp Shelby, Miss.
MITCHELL, George J., 1st Lieut., Meridian, Miss., Camp Blanding, Fla.
MONTAGNET, J. M., Jr., 1st Lieut., New Orleans, Camp Forrest, Tenn.
MORROW, Arch S., 1st Lieut., Jacksonville, Fla., Fort Bragg, N. C.
MOTTY, Jules Stell, 1st Lieut., New Orleans, Camp Davis, N. C.
MURPHY, Robert J., Jr., 1st Lieut., Durham, N. C., Fort Bragg, N. C.
NETTERVILLE, Rush E., 1st Lieut., New Orleans, Camp Croft, S. C.
NICHOLS, Ralph Gibbs, 1st Lieut., Knoxville, Tenn., Camp Polk, La.
NILES, George A., Jr., 1st Lieut., Atlanta, Ga., Camp Davis, N. C.
PARKS, Lorenzo Lynn, Major, Jacksonville, Fla., Headquarters 4th Army Corps, Jacksonville, Fla.
PARNELL, Homer S., Jr., 1st Lieut., New Orleans, Camp Polk, La.
PARROTT, John H., 1st Lieut., Camp Shelby, Miss., Fort Benning, Ga.
PASTERNAK, Morris, 1st Lieut., New Orleans, Fort Jackson, S. C.
PATTERSON, McLeod, 1st Lieut., New Orleans, Camp Croft, S. C.
PEPE, John Luke, 1st Lieut., New Orleans, Fort Jackson, S. C.
PETERSON, Bedford F., 1st Lieut., Bolivar, Tenn., Camp Wheeler, Ga.
PHILLIPS, Benjamin J., 1st Lieut., New Orleans, Fort Jackson, S. C.
PHILLIPS, James B., Jr., 1st Lieut., Chattanooga, Tenn., Camp Croft, S. C.
PINSON, Harry D., 1st Lieut., Augusta, Ga., Camp Croft, S. C.
PIZZOLATO, Philip, 1st Lieut., New Orleans, Camp Croft, S. C.
POLITES, Nicholas, 1st Lieut., Wilmington, N. C., Camp Polk, La.
POLLARD, Edward V., 1st Lieut., Parsons, Tenn., Fort Bragg, N. C.
POPE, Madison R., 1st Lieut., Charleston, S. C., Fort Bragg, N. C.
RAGGIO, Francis W., Jr., 1st Lieut., New Orleans, Camp Wheeler, Ga.
RAGSDALE, William E., Jr., 1st Lieut., Memphis, Tenn., MacDill Field, Fla.
RANCK, Edward Buford, 1st Lieut., Atlanta, Ga., Camp Forrest, Tenn.
RAVENEL, Joseph A., 1st Lieut., New Orleans, MacDill Field, Fla.
RAY, Russell B., 1st Lieut., Memphis, Tenn., MacDill Field, Fla.
RHAME, Delmar O., Jr., 1st Lieut., Clinton, S. C., Camp Livingston, La.
ROBINSON, Edward B., Jr., 1st Lieut., Birmingham, Ala., Camp Blanding, Fla.
SCHONLAU, James W., 1st Lieut., Shreveport, La., Camp Forrest, Tenn.
SILBERMAN, Donald J., 1st Lieut., Birmingham, Ala., Camp Claiborne, La.
SIMMONS, William G., 1st Lieut., Emory, Ga., MacDill Field, Fla.
SMERZNAK, John J., 1st Lieut., Concord, N. C., Camp Livingston, La.
SMITH, Harold M., 1st Lieut., Savannah, Ga., Camp Wheeler, Ga.
SPITZBERG, R. H., 1st Lieut., Mobile, Ala., Camp Forrest, Tenn.
STANDER, Alvin A., 1st Lieut., Baton Rouge, La., Camp Davis, N. C.

YOUNG, John D., 1st Lieut., Atlanta, Ga., MacDill Field, Fla.

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Sixth Corps Area, which comprises the states of Wisconsin, Illinois and Michigan:

SIXTH CORPS AREA

ACOCKS, James R., 1st Lieut., Houghton, Mich., Selfridge Field, Mich.
ALBI, Raphael W., 1st Lieut., Lake City, Mich., Station Complement, Camp Wheeler, Ga.
ALBIN, Meyer S., 1st Lieut., Cadillac, Mich., Station Complement, Croft, S. C.
ALLEGRETTI, Joseph E., Captain, Chicago, Station Complement, Camp Axel, Ben John, 1st Lieut., Madison, Wis., Station Complement, Camp Jackson, S. C.
BACHHUBER, Edward A., 1st Lieut., Mayville, Wis., Station Hospital, Fort Sill, Okla.
BENISON, Arthur L., 1st Lieut., Edmore, Mich., Station Complement, Camp Wheeler, Macon, Ga.
BERKELHAMER, Ralph C., 1st Lieut., Chicago, Station Complement, Camp Davis, N. C.
BUSCAGLIA, Chris J., 1st Lieut., Ypsilanti, Mich., 11th Station Hospital, Fort Custer, Mich.
BRAND, Ashley M., 1st Lieut., Chicago, 210th Corps Area (Anti-aircraft), U. S. National Guard, Fort Sheridan, Ill.
BROOKS, Lewis C., Captain, Freeport, Ill., 27th Division, Fort Jackson, S. C.
BROWNELL, Paul G., 1st Lieut., Detroit, Station Complement, Fort CHRISTENSON, Albert W., Lieut. Col., Rockford, Ill., Savanna Ordnance Depot, Proving Ground, Ill.
CITRON, Robert R., 1st Lieut., Peoria, Ill., 24th Infantry, Fort Benning, Ga.
CLAUDON, Dann B., 1st Lieut., Jefferson, Wis., Station Hospital, Camp Grant, Ill.
CLAXTON, Wilbert T., 1st Lieut., Britton, Mich., Station Hospital, Camp Sill, Okla.
DIETRICH, Hervey W., 1st Lieut., Madison, Wis., Medical Detachment, 7th Cavalry, Fort Bliss, Texas.
DUDLEY, Erwin F., Major, Decatur, Ill., 11th Station Hospital, Fort Custer, Mich.
DUNN, Marion F., 1st Lieut., Waukegan, Ill., Infirmary, Medical Replacement Center, Camp Grant, Ill.
EGGERS, John F., 1st Lieut., Sycamore, Ill., 27th Division, Medical McClellan, Ala.
ESPEY, Hugh S., 1st Lieut., Zenia, Ohio, Station Complement, Fort Croft, S. C.
FALICK, Mordecai L., 1st Lieut., Detroit, Station Complement, Camp Jackson, S. C.
FEIGELMAN, Meyer J., 1st Lieut., Detroit, Station Complement, Camp Wheeler, Macon, Ga.
GLOSS, Kenneth E., 1st Lieut., Crystal Falls, Mich., Air Corps Basic Flying School, San Angelo, Texas.
HALE, Claude E., 1st Lieut., Marshall, Mich., Station Hospital, Fort Sam Houston, Texas.
HANNAN, Kenneth D. L., 1st Lieut., Prairie Du Sac, Wis., 27th Division, Fort McClellan, Ala.
HANSEN, Harvey C., 1st Lieut., Battle Creek, Mich., 24th Infantry, Fort Benning, Ga.
HARPER, Jesse T., Captain, Detroit, Station Hospital, Fort Custer, Ala.
HORA, James L., 1st Lieut., Chicago, 27th Division, Fort McClellan, Ala.
HOROWITZ, Samuel F., 1st Lieut., Bay City, Mich., Station Complement, Camp Croft, S. C.
HUTCHISON, William A., 1st Lieut., Chicago, Station Complement, Selfridge Field, Mich.
IVKOVICH, Paul, 1st Lieut., Evart, Mich., Station Complement, Camp Croft, S. C.
KANTER, Myron F., 1st Lieut., Chicago, Station Complement, Camp Davis, N. C.
KNAPP, Joseph L., 1st Lieut., Traverse City, Mich., Station Complement, Camp Croft, S. C.

LIVINGSTON, A. Edward, 1st Lieut., Denver, Station Hospital, Fort Sill, Okla.
LOGSDON, Robert E., 1st Lieut., Mount Sterling, Ill., Station Hospital, Fort Sill, Okla.
LONGWELL, Charles W., 1st Lieut., Nashville, Ill., Station Hospital, Fort Bliss, Texas.
LOOMIS, Frederic G., 1st Lieut., Waterloo, Iowa, Station Complement, Camp Shelby, Miss.
MILLER, Harold A., 1st Lieut., Saline, Mich., 23d Evacuation Hospital, Fort Custer, Mich.
MAERCKLEIN, Arthur G., Captain, Union Grove, Wis., Station Complement, Camp Davis, N. C.
MOORE, Gregory P., Captain, Cadillac, Mich., 94th Engineer Battalion, Fort Custer, Mich.
MUMLER, William C., 1st Lieut., Chicago, Station Hospital, Fort Sheridan, Ill.
MUSSELMAN, Merle M., 1st Lieut., Ann Arbor, Mich., Station Hospital, Fort Bliss, Texas.
NESBITT, William E., 1st Lieut., Alpena, Mich., Station Complement, Camp Wheeler, Ga.
OLTMAN, Diedrich L., 1st Lieut., East Moline, Ill., Station Hospital, Fort Sam Houston, Texas.
OSBORNE, Charles E., 1st Lieut., Vicksburg, Mich., Station Complement, Camp Wheeler, Ga.
PALEMO, Amiel L., 1st Lieut., Chicago, Station Hospital, Fort Bliss, Texas.
PERNWORTH, Paul H., 1st Lieut., Venice, Ill., Scott Field, Ill.
PHILLIPS, Francis J., 1st Lieut., Detroit, Station Complement, Camp Croft, S. C.
POINDEXTER, Marlin H., Jr., 1st Lieut., Milwaukee, Station Complement, Camp Croft, S. C.
PRZYGOCKI, Stanley F., Captain, Chicago, Station Complement, Camp Davis, N. C.
RICHARDS, Francis L., 1st Lieut., Kearney, Neb., Station Complement, Camp Davis, N. C.
RICKETTS, Frederick J., 1st Lieut., Sadorus, Ill., Selfridge Field, Mich.
RODHOLM, Ansgar K., 1st Lieut., Chicago, Station Complement, Camp Croft, S. C.

AVIATION MEDICINE

The Los Angeles County Medical Association devoted its May 29 meeting to a discussion of aviation medicine. Dr. Isaac H. Jones opened the discussion; other speakers participating in the discussion were Lieut. Col. Ernest F. Harrison, flight surgeon, U. S. Army Air Corps; Comdr. Joel J. White, flight surgeon, U. S. Navy; Lieut. Comdr. John H. Korb, flight surgeon, U. S. Navy, and Dr. Robert W. Langley.

MEDICAL OFFICERS WHO DESIRE TO ATTEND MEETINGS

The War Department has announced that officers of the medical department who desire to attend meetings of any of the national societies pertaining to their profession will be permitted to attend these meetings on detached service status and without expense to the government, provided their services are spared.

ORGANIZATION SECTION

OFFICIAL NOTES

RADIO PROGRAM. AT CLEVELAND

The customary arrangements for radio broadcasts in connection with the annual session of the American Medical Association, at Cleveland, have been made.

The weekly dramatized program *Doctors at Work*, on the Blue network of the National Broadcasting Company, will close with the broadcast scheduled for Wednesday, June 4 at 10:30 p. m., Eastern daylight saving time, with a program entitled "March of Medicine, 1941." The dramatic episodes and music will originate at Chicago, as usual, but the summary will be delivered from the studios of WHK at Cleveland.

In addition, the following broadcasts have been scheduled on National Broadcasting Company and Columbia Broadcasting System networks, and Cleveland local stations:

WTAM-NBC. Monday, June 2. 7:45 p. m., eastern daylight saving time. Dr. N. B. Van Etten, New York. Medical progress and national defense.
WTAM. Wednesday, June 4. 10:10:15 p. m., eastern standard time. Dr. Lowell S. Selling, Detroit. Psychology of traffic offenses.
WTAM. Tuesday, June 3. 10:15-10:30 p. m., eastern standard time. Dr. John D. Currence, New York. Arthritis.
WTAM-NBC (Blue). Friday, June 6. 10:10:15 p. m., eastern daylight saving time. Dr. W. W. Bauer, Chicago. Convention news.

WHK. Tuesday, June 3. 11:15-11:30 a. m., eastern standard time. Dr. M. S. White, Randolph Field, Texas. Medical aspects of flying.
WHK. Thursday, June 5. 11:15-11:30 a. m., eastern standard time. Dr. J. West Mitchell, Sewickley, Pa. Diabetes.
WGAR-CBS. Wednesday, June 4. 9:15-9:30 p. m., eastern standard time. Dr. Frank H. Lahey, Boston. Progress in medicine and surgery.
WGAR-CBS. Thursday, June 5. Dr. W. W. Bauer. Science Service program. See local papers for time.
WGAR. Tuesday, June 3. 4:15-4:30 p. m., eastern standard time. Dr. Grover C. Penberthy, Detroit. The treatment of burns.
WGAR. Thursday, June 5. 4:15-4:30 p. m., eastern standard time. Dr. Gordon B. New, Rochester, Minn. The treatment of face injuries.
WCLE. Wednesday, June 4. 1:15-1:30 p. m., eastern standard time. Dr. Walter C. Alvarez, Rochester, Minn. Food allergies.
WCLE. Tuesday, June 3. 1:15-1:30 p. m., eastern standard time. Dr. G. Wilse Robinson Jr., Kansas City, Mo. Old age.
WTAM. Tuesday, June 3. 4:45-5 p. m. Woman's Club of the Air. Miss Jane Weaver, Cleveland, and Dr. W. W. Bauer, Chicago.
WTAM. Sunday, June 1. 2:2-15 p. m., eastern standard time. Dr. Morris Fishbein, Chicago. Preview of the convention.

Special broadcasts for the children in Cleveland and suburban schools have been scheduled on the short wave radio station WBOE, operated by the Cleveland Board of Education, as follows:

1. Wednesday, June 4. 2:10-2:25 p. m., eastern standard time. Dr. M. E. Obermayer, Chicago. Skin and adolescence.
2. Thursday, 10:30-10:45 a. m. Dr. Sara M. Jordan, Boston. Constipation and laxatives.

MEDICAL ECONOMIC ABSTRACTS

MEDICAL CARE FOR THE AGED IN WASHINGTON

A REPORT BY THE BUREAU OF
MEDICAL ECONOMICS

At the election held in the state of Washington, Nov. 5, 1940 Initiative No. 141 providing for an old age pension of not less than \$40 a month including any other income of the recipients was adopted by a vote of 358,009 with 258,819 against it. It is expected that the federal government will contribute one half, or \$20, and the measure provides that in case the federal contribution is increased the state shall add a sum equal to whatever the federal subsidy may be. A section of the law which seems to have attracted little attention when the initiative was under discussion says:

In addition to Senior Citizen Grants, the Department shall provide for those eligible medical, dental, surgical, optical, hospital and nursing care by a doctor of recipient's own choosing; and shall also provide artificial limbs, eyes, hearing aids and other needed appliances.

Although at the time the law was enacted there were only 45,000 persons receiving an old age pension, the Social Security Department has since accepted 15,000 more, making a total of 60,000 old age recipients. It is now thought that the total number of recipients may reach 70,000 or possibly 75,000. The state must bear the entire expense of the medical care furnished. When the budget was first made up in December 1940 an item of \$4,320,000 was included. The Washington State Medical Association after studying the provisions of the act concluded that a minimum of \$9,700,000 would be required to provide medical care to 45,000 recipients. The governor finally recommended an appropriation of \$5,320,000, which in his opinion would be sufficient. Of this amount 50 per cent, or \$2,660,000, was definitely earmarked for doctors' services. The attorney general ruled that the word "doctor" would include doctors of medicine, dentists, osteopaths, chiropractors and chiropodists.

Information taken from Initiative Measure 141, the mimeographed regulations for the conduct of the act, *Northwest Medicine* 40:151 (April) 1941, and a letter from Dr. V. W. Spickard, secretary-treasurer of the Washington State Medical Association.

The act is to be administered by the State Medical-Dental Board of the State Department of Social Security. Nine members of this board have already been appointed, and an additional one is to be appointed by the State Hospital Association. Of those appointed, two physicians were approved by the Washington State Medical Association, two physicians appointed by the State Department of Social Security, two dentists approved by the State Dental Association, one physician by the State Department of Health, one registered nurse to represent the State Nurses Association and one layman who is assistant to the director of the State Department of Social Security. An interesting feature of the administrative machinery is that the agencies chosen for providing the medical service are the medical service bureaus operated by the county medical societies. There are fourteen of these listed in the regulations. A majority of these provide service in two or more counties, so that almost the entire state of Washington is within the field covered by some medical-dental service bureaus. The plan operates under a fee schedule submitted by the Washington State Medical Association as follows:

First office or home visit.....	\$3.00
Subsequent home visits.....	2.50
Subsequent office visits.....	2.00
Night calls from 9 p. m. to 7 a. m.....	4.50
Consultation	3.00
Roentgenograms and laboratory work, except in emergencies, shall be authorized by the Medical Service Bureau and shall be at the State Department of Labor and Industries' rates and subject to the same proration as other fees.	
Eye examinations with refraction.....	5.00

However, this fee schedule is to be paid on the unit system by which the available funds are to be prorated monthly. The medical service bureaus are permitted to make a service charge not to exceed 7 per cent of the bills submitted. There is to be free choice of physicians, osteopaths or chiropractors among all those who agree to abide by the regulations. Hospital care, however, will be provided in county hospitals, and medical care within the hospital will be given by the hospital staff and not by the patient's chosen physician. Prescriptions are not

ORGANIZATION SECTION

Jour. A. M. A.
May 31, 1941

paid for. Medical and optical care will be given. In acute illnesses recipients are limited to seven visits, after which additional authorization must be obtained. In chronic cases care is limited to one visit a week for a period not to exceed three months. Appliances, including glasses, will be provided through the county welfare department within the limits of available funds.

THE BRITISH REGIONAL HOSPITAL SCHEME

In January the Nuffield Provincial Hospital Trust published a proposed scheme for a regional reorganization of British hospitals, which has given rise not only to a great deal of discussion but to some important steps toward its realization.¹ The policy of the trust is briefly described as follows:

- (a) To divide the country into a number of regions with the object of establishing in each an organization of hospital and health services through a regional council representing the voluntary hospitals and local authorities within the region. It is intended that a hospital or group of hospitals associated with a university medical school should be the regional center whenever possible and the region should be subdivided into two, three or more divisions based on a "key" hospital, each with a divisional hospitals council appointing representatives on the regional council.
- (b) To give financial aid to the initiation and support of these regional councils.
- (c) To allot, on application, to such regional or divisional councils sums of money for the promotion of hospital and health services, medical research and teaching which, in the opinion of the regional council, are necessary to meet the needs of the population in the region.

Regional hospital councils have already been constituted in three different parts of the country. The regional councils in these districts have undertaken the following activities:

- (a) Survey of hospital services on a regional or divisional basis with the object of preparing a comprehensive report on the existence of duplication or overlapping or the necessity for the development of new services or the extension of services already available.
- (b) Organization of a system of transfer of patients from the "key" hospital to other hospitals within the division after operation or for the

1. Buzzard, Sir E. Farquhar, Chairman of the Medical Advisory Council of the Trust: Post-War Hospital Policy, The Nuffield Provincial Hospital Trust at Work, *Lancet* 1: 155 (Feb. 1) 1941.

continuation of treatment. The result of this arrangement is to reduce the period of occupation of beds in the "key" hospital, thus freeing these beds for other patients requiring such specialist treatment as is obtainable in other hospitals in the division. It is hoped that this system will reduce waiting lists and thus be of great benefit to the community.

(c) Organization of a divisional blood transfusion services.

(d) This arrangement of a divisional system of ear, nose and throat clinics. of district hospitals in affiliation to the ear, nose and throat department of the "key" hospital in the division.

(e) Proposals are under consideration for (1) regional or divisional accident services, (2) regional pathologic services and, in connection with the latter proposals, it is considered that a pathologic service is not only urgently necessary but is peculiarly well adapted to regional organization.

The plan assumes the formation of a primary or key hospital or group of hospitals which should, if possible, be connected with a medical school. The smaller hospitals, generally with less than twenty beds, within each region are to be linked up with the key hospitals with the understanding that the smaller hospital should undertake the care of patients from their neighborhood "who do not need more special skill than can be obtained locally or by visits of specialists from the center and who are ready to leave the key hospital and are not yet fit to return to their homes." It proposed that the key hospitals shall be linked with the smaller institutions by a system of periodic visits by the consulting staff of the key hospitals and the organization of special services, such as pathologic, accident and cancer, on a regional basis.

The growth of municipal hospitals since the local government act of 1929 has proceeded to the point at which they now have more beds than the voluntary hospitals. It is proposed to include both municipal and voluntary hospitals in the plan and to establish various branches of the medical profession. These advisory committees will have the responsibility of advising the regional councils with regard to the development, the limitation or the curtailment of services in order to avoid wasteful overlapping or competition.

MEDICAL LEGISLATION

STATE MEDICAL LEGISLATION

Connecticut

Bill Introduced.—Substitute for H. 1813 proposes to permit a registered physician to advise and prescribe for married persons regarding marriage problems and to give such persons access to medical information and supplies conducive to health, notwithstanding the restrictions contained in the laws of Connecticut relating to the use of drugs or instruments for the prevention of conception.

Florida

Bill Introduced.—H. 1230, to amend the medical practice act, proposes to eliminate those provisions which require that, of the ten members of the board of medical examiners, five shall be allopathic physicians, three, eclectic physicians and two, homeopathic physicians.

Illinois

Bill Introduced.—H. 809 proposes to enact a new chiropody practice act. The bill proposes that "A person practices chiropody within the meaning of this Act who offers or undertakes, by any means or method, to diagnose, recommend, or prescribe for any ailment or supposed ailment of the human foot of another or who offers or undertakes the local, medical, mechanical or surgical treatment of any ailment or supposed ailment of the human foot of another including general manipulative massage, whether manual, mechanical or electrical, except amputation of the foot or toes or the use of anesthetics other than local, or the use of drugs or medicines other than local anesthetics."

DISTRICT OF COLUMBIA

Bill Introduced.—H. R. 4786, introduced by Representative Randolph, West Virginia, proposes to require examination and laboratory tests for syphilis, gonorrhea and tuberculosis of all applicants for marriage licenses in the District of Columbia.

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 4258 has passed the House, providing that whoever brings on board or has in his possession or control on board any vessel of the United States any narcotic drug not constituting a part of the cargo entered in the manifest or part of the ship stores shall be subject to fine or imprisonment, or both. H. R. 4293 has passed the House, providing that any person who furnishes blood for transfusion into the veins of any person entitled to undergo treatment at government expense or who shall furnish blood for blood banks or for other scientific and research purposes shall be entitled to be paid therefor a sum not to exceed \$50 for each blood withdrawal. The Senate Committee on Public Buildings and Grounds has concluded hearings on H. R. 4545, a bill to provide for the acquisition and equipment of public works made necessary by the defense program, including the acquisition and equipment of hospitals. S. 194 has been passed by the Senate, proposing to authorize research by the United States Public Health Service relating to the cause, diagnosis and treatment of dental diseases.

Bills Introduced.—S. 1527, introduced by Senator Smathers, and H. R. 4789, introduced by Representative Wene, both of New Jersey, propose a federal appropriation of \$4,000,000 to construct a veterans' hospital in New Jersey with a capacity of not less than one thousand beds. H. R. 4770, introduced by request, by Representative May, Kentucky, proposes to amend the Selective Training and Service Act so as to authorize the President to provide for the deferment, by age group, from training and service under the act of those men whose ages are such that he finds that deferment to be advisable in the national interest. H. R. 4793, introduced by Representative O'Brien, Michigan, proposes an annual appropriation of \$50,000,000 to provide rehabilitation and employment for needy physically handicapped persons.

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)
ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 2543.

ILLINOIS

Survey of Crippled Children.—Information has been collected on more than 32,000 crippled children in the state through a survey now nearing completion by the WPA and the state division for handicapped children. Details cover the crippling condition, race, sex, age and county of residence, providing data on an exceptionally large group of cases for research studies and establishing the basis for a more nearly complete current registry of crippled children throughout the state. The maintenance of a current registry is required by the U. S. Children's Bureau of the state division charged with giving services to crippled children under the provisions of the social security act.

Chicago

Hospital News.—Construction has been started on a new \$300,000 addition to the Mount Sinai Hospital to house the new pediatric department, semiprivate facilities for white collar workers and deluxe private room accommodations. A new morgue and necropsy room and a new ambulance entrance with adjoining emergency room will also be built.

Meeting of Academy of Sciences.—Dr. Nathan Smith Davis III was reelected president of the Chicago Academy of Sciences at its eighty-fourth annual meeting, April 14. The speaker of the evening, Dr. Andrew C. Ivy, whose address was entitled "The Gastrointestinal Hormones and Their Uses," was elected an honorary member of the academy.

University News.—Reuben L. Kahn, Sc.D., assistant professor of bacteriology and serology in charge of clinical laboratories, University of Michigan Medical School, Ann Arbor, lectured at Mercy Hospital, April 25, under the auspices of the department of preventive medicine, public health and bacteriology, Loyola University School of Medicine. His subject was "Newer Observations in the Serology of Syphilis."

Personal.—Dr. James H. Hutton has been appointed state health consultant of the National Youth Administration for Illinois; he will direct the procedure for physical examinations of NYA youth in the state.—Dr. Earl E. Kleinschmidt, associate professor and chairman of the department of public health, preventive medicine and bacteriology at Loyola University School of Medicine, has been granted leave of absence for three months to work in Washington making plans for the protection and guidance of students employed in vocational training for defense work in industry.

The Capps Prize.—The Institute of Medicine of Chicago offers a prize of \$400 for the most meritorious investigation in medicine or in the specialties of medicine. The investigation may be also in the fundamental sciences, provided the work has a definite bearing on some medical problem. Competition is open to graduates of Chicago medical schools who completed their internship or one year of laboratory work in 1939 or thereafter. Manuscripts must be submitted to the secretary of the institute, 86 East Randolph Street, not later than December 31. If no paper is deemed worthy of the prize, the award may be withheld at the discretion of the board of governors.

IOWA

Personal.—Dr. Wallace S. Petty, Sioux City, has resigned as health officer of Woodbury County. He has been succeeded by Dr. John A. Cowan, who has been acting director of public health for Sioux City and Woodbury County.—Dr. James E. Dyson has been appointed acting director of health of the public schools of Des Moines. He fills the vacancy that occurred when Dr. Fred Moore died recently. Dr. Dyson graduated at the University of Minnesota Medical School, Minneapolis, in 1916.—Dr. David T. Nicoll, Mitchellville, was recently made a life member of the Polk County Medical Society on his completion of fifty years in the practice of medicine.

Society News.—The Calhoun County Medical Society was addressed in Rockwell City, April 15, by the following physicians from Council Bluffs; Drs. McMicken Hanchett, "Treatment of Tetanus"; Aldis A. Johnson, "Newer Procedures in Diagnostic Medicine," and Jack V. Treynor, "Treatment of Subacute Throat Infections."—Dr. Henry G. Decker, Des Moines, discussed "Relief of Intractable Pain" before the Humboldt County Medical Society in Humboldt, April 17.—Dr. Rolland Russell Best, Omaha, addressed the Johnson County Medical Society, April 2, in Iowa City on "Applica-

CALIFORNIA

Society News.—The Junior Section of the Los Angeles County Medical Association and the Junior Bar Association of Los Angeles held a joint symposium, May 15.—Dr. Joseph Brennmann, Los Angeles, discussed "Appendicitis in Childhood" before the Hollywood Academy of Medicine, May 8.

Flower Show Society.—The Bulletin of the Los Angeles County Medical Association announces that a Physicians' Flower Show Society will be formed, evidencing the success of the society's first flower show, held April 16-17. A section will be created within the new society especially for the wives of members who are interested in flower arrangements. The bulletin also announced a two day exhibit to be held this fall during the chrysanthemum season.

DELAWARE

Appointments at du Pont Institute.—Dr. Daniel Murray Angevine, assistant professor of pathology at Cornell University Medical College, New York, was appointed bacteriologist and pathologist at the Alfred I. du Pont Institute of the Nemours Foundation at Wilmington, effective May 1. According to *Science*, other appointments that have been made recently include Dr. Lee E. Farr, associate in medicine at the Hospital of the Rockefeller Institute for Medical Research, New York, as director of research and pediatrician-in-chief. He became at the same time visiting associate professor of pediatrics at the University of Pennsylvania School of Medicine, Philadelphia. Dr. Douglas A. MacFadyen, associate in chemistry at the Rockefeller Hospital, has been appointed chief of biochemistry at the du Pont Institute and visiting assistant professor of pediatrics at Pennsylvania.

FLORIDA

Personal.—Dr. Leland H. Dame, Jasper, has been named health officer for Highlands and Glades counties, succeeding Dr. Erwin F. Hoffman, Sebring, resigned.—W. C. McLeod, D.D.S., Pensacola, has been appointed a member of the merit system council for the state board of health and the crippled children's commission; the council is to establish general policies for the administration of the merit system under which employees of the board and commission will work.

State Medical Election.—Dr. Gilbert S. Osincup, Orlando, was named president-elect of the Florida Medical Association at its annual meeting recently and Dr. Walter C. Jones Jr., Miami, was installed as president. Other officers of the association include Drs. Luther W. Holloway, Jacksonville, Fredrick K. Herpel, West Palm Beach, Walter C. Payne, Pensacola, vice presidents; Dr. Shaler A. Richardson, Jacksonville, secretary-treasurer, and Stewart G. Thompson, D.P.H., Jacksonville, managing director. The 1942 session will be in West Palm Beach.

IDAHO

State Medical Meeting in Sun Valley.—The forty-ninth annual session of the Idaho State Medical Association will be held at the Sun Valley Lodge, Sun Valley, June 18-21, under the presidency of Dr. Abram M. Newton, Pocatello. Guest speakers will include the following members of Stanford University School of Medicine, San Francisco:

Dr. William Dock, Etiology and Pathology of Hypertension; Causes of Peptic Ulcer and Their Control; Cancer from the Pathologist's Angle.
Dr. David A. Ryland, Management of Hypertension; Management of Bright's Disease; Nature and Treatment of Obesity.
Dr. Maurice L. Tainter, Practical Application of Sympathomimetic Drugs Including Benzadrine; New Remedies Used in Gastrointestinal Disease, Including Colloid Laxatives; Medicinal Treatment of Asthma and Other Allergies; Present Status of Sulfonamide Derivatives.
Dr. Carleton Mathewson Jr., Diagnosis and Treatment of Bowel Obstruction; Surgical Treatment of Peptic Ulcer; Ambulatory Treatment of Fractures of the Lower Extremity.
Dr. Nelson J. Howard, The Endocrine Basis of Benign Lesions of the Breast; Pathology and Clinical Features of Disease of Tendons; Common Injuries to the Heart.

In addition, instruction courses will be conducted by members of the state medical association. A round table luncheon is planned for each day. Golf and bowling tournaments are also on this year's program.

MEDICAL NEWS

JOUR. A. M. A.
MAY 31, 1941

tion of the Biliary Flush in the Treatment of Biliary Tract Disease."—Dr. Irvine McQuarrie, Minneapolis, discussed "Experiments of Nature in Clinical Medicine" before the Linn County Medical Society, April 10, in Cedar Rapids.

MAINE

Society News.—A symposium on lesions of the stomach and duodenum was presented before the Portland Medical Club, April 1, by Drs. Elton R. Blaisdell and Jack Spencer; papers were presented by Drs. George A. Tibbetts and Isaac M. Webber on "Acute Surgical Emergencies" and "Gastric Resection" respectively. —Dr. Donald Munro, Boston, discussed "Immediate Treatment of Head Injuries" before the Kennebec County Medical Association in Augusta, April 17. —The Knox County Medical Association was addressed in Rockland, April 8, by Dr. Katherine S. Andrews, Boston, on "Gastric Cancer." —The York County Medical Association devoted its meeting in Sanford, April 2, to a panel discussion on endocrine dysfunction. Participating were Drs. James Carswell Jr. and Howard L. Apollonio, Camden, and Paul A. Jones, Union.

MASSACHUSETTS

The Henry Jackson Lecture.—Comdr. John R. Poppen, bureau of aeronautics, U. S. Navy Department, Washington, D. C., delivered the Henry Jackson Lecture for 1941, under the auspices of the New England Heart Association, May 2. His subject was "Cardiovascular Problems in Aviation Medicine."

Fellowship Awarded.—Dr. Israel Kapnick, Providence, R. I., now studying at the Massachusetts General Hospital, Boston, has been awarded the Louis E. Kirstein Fellowship at Harvard Medical School for the summer of 1941. The fellowship was established through a gift of \$28,550 made to Harvard University by eighty-nine friends of Mr. Kirstein, vice president of William Filene's Sons Company, in honor of his seventieth birthday and in recognition "of their affection for him as a man and their admiration of him as a humanitarian." In accordance with the request of the donors, the fund remains active so that additions may be made to it from time to time. Dr. Kapnick graduated at Harvard in 1938.

MINNESOTA

The Root Medical History Lecture.—Dr. Arno B. Luckhardt, professor of physiology, Department of Medicine, University of Chicago, delivered the annual William W. Root Medical History Lecture at the University of Minnesota Medical School, Minneapolis, April 29. The lecture is sponsored by Alpha Omega Alpha Fraternity. His subject was "Dr. William Beaumont and the Medical Epic of Northwest Territory."

University News.—A course in roentgen diagnosis of non-tuberculous diseases of the lungs and pleura was offered at the Center for Continuation Study, University of Minnesota, Minneapolis, May 22-24. Enrollment was limited to physicians with special training in radiology. —The Carnegie Corporation has made a grant of \$5,000 to the University of Minnesota for the continued support of investigations of viruses in relation to cell growth, conducted under the direction of Dr. Robert G. Green, professor of bacteriology and immunology at the medical school.

Society News.—Carl G. Hartman, Ph.D., Baltimore, addressed the Hennepin County Medical Society, Minneapolis, April 7, on the "Use of Gonadotropic Substances in Gynecology (based largely on controlled experiments in the monkey) and Administration of Steroidal Hormones in the Form of Pellets (Estrogen Therapy) and Possible Carcinogenesis." —The Minnesota Pathological Society was addressed in Minneapolis, April 12, by Drs. Robert G. Green and Charles A. Evans on "Vitamin B Deficiency from Fish Diets" and Elexious T. Bell, "Pathologic Physiology of the Kidney." All are of Minneapolis. —Dr. Max W. Alberts, St. Paul, discussed "Complicating Factors Associated with Cancer of the Large Bowel" before the Minnesota Academy of Medicine in St. Paul, April 9.

NEBRASKA

Lecture by Dr. Dam.—Professor Henrik Dam of the Biochemical Institute, Copenhagen, Denmark, addressed a special meeting of the Lancaster County Medical Society, Lincoln, April 10, on "Clinical Aspects of Vitamin K."

Personal.—Dr. George E. Charlton, superintendent of the Norfolk State Hospital, Norfolk, was recently honored by a reception marking his twenty-fifth year of association with the hospital. He was appointed superintendent in 1916 and has

served continuously since that time except for two years when he was superintendent at the Hastings State Hospital at Ingleside.

NEW YORK

Society News.—Dr. Sumner L. S. Koch, Chicago, was the guest speaker at a meeting of the Western New York Surgical Association at Jamestown, April 10, on "Injuries of the Hand." An afternoon session was devoted to round table discussions. —Dr. Cary Eggleston, New York, addressed the Medical Society of the County of Albany, April 23, on "Current Concepts of Coronary Artery Disease and Myocardial Infarction." —Dr. Howard T. Karsner, Cleveland, addressed the Onondaga County Medical Society in a joint meeting with Alpha Omega Alpha, Syracuse, April 1, on "Calcific Sclerosis of the Aortic Valve." —Dr. Varzstad H. Kazanjian, Boston, addressed a joint meeting of the Syracuse Academy of Medicine and the Eye, Ear, Nose and Throat Club, April 15, on "Traumatic Surgery of the Face and Jaws, Including War Injuries."

New York City

Personal.—Dr. James L. McCartney, formerly with Sharp & Dohme, Philadelphia pharmaceutical manufacturers, has been appointed medical director of William R. Warner & Co., Inc., and associated organizations. —Dr. Paul W. Lapidus has been appointed adjunct professor of orthopedic surgery and assistant attending orthopedic surgeon in the New York Polyclinic Medical School and Hospital.

Squibb Award Goes to Anatomist.—Philip E. Smith, Ph.D., professor of anatomy at Columbia University College of Physicians and Surgeons, was presented with the annual Squibb Award during the session of the Association for the Study of Internal Secretions in Atlantic City, May 2-3. The award is given annually by E. R. Squibb and Sons to a "distinguished contributor to the field of endocrinology." Dr. Smith received his degree at Cornell University in 1910. He subsequently served on the faculties of Cornell, California and Stanford universities, becoming professor at Columbia in 1927.

OHIO

Alumni Reunion.—The annual reunion of the Alumni Association of the University of Cincinnati College of Medicine will be held in Cincinnati, June 7. Hospital and clinic demonstrations will be presented during the day and the annual banquet will be held in the evening at the Sinton Hotel. The banquet speaker will be Dr. Clay Ray Murray, associate professor of surgery, Columbia University College of Physicians and Surgeons, New York. Following the banquet there will be a reception and dance in honor of the graduating class. Reservations should be made at the alumni office at the university or at the college of medicine. Dr. Mabel E. Gardner, Middletown, is president of the alumni association.

Dr. Upham Retires as Dean.—Dr. John H. J. Upham, dean of Ohio State University College of Medicine, Columbus, is to be the guest of honor at a testimonial dinner given June 6 at the Neil House by the faculty on the occasion of his retirement. Dr. Upham is retiring because of his retirement rule of the university. He first joined the faculty in 1897; in 1908 he became professor of medicine and served in that department until he was appointed dean in 1927. Dr. Upham has held many state and national medical offices. In Ohio he was president of the Columbus Academy of Medicine in 1919, president of the Ohio State Medical Association in 1914 and editor of the *Ohio State Medical Journal* from 1907 to 1913. Since 1913 he has been a member of the state board of medical examiners and since 1930 a member of the National Board of Medical Examiners. Dr. Upham was elected to the Judicial Council of the American Medical Association in 1922, then to the Board of Trustees in 1923, serving until 1935, the last two years of that period as chairman of the Board. He was President of the Association for the year 1937-1938.

PENNSYLVANIA

District Meeting.—A meeting of the Seventh Councilor District of the Medical Society of the State of Pennsylvania was held in Williamsport, May 9, with Drs. David E. Hemington, Uniontown, and Walter C. Alvarez, Rochester, Minn., as speakers at the morning session on "Better Medical Care for Workers in Small Industries" and "Puzzling Types of Abdominal Pain" respectively. In the afternoon Dr. Alvarez addressed a joint meeting with the woman's auxiliary of the district on "Why Women Get Nervous." Fifty year awards were made by the president of the state society, Dr. Francis

F. Borzell, Philadelphia, to Drs. Oliver W. H. Glover, Laurelton, Robert B. Tule, Milton, and Lewis E. Wolfe, New Berlin. Dr. Borzell and Dr. Lewis T. Buckman, Wilkes-Barre, president-elect of the state society, discussed subjects of current interest.

Philadelphia

Personal.—Dr. Donald C. Smelzer, director of the Graduate Hospital of the University of Pennsylvania since 1930, will resign, June 1, to become managing director of the Germantown Dispensary and Hospital, according to *Modern Hospital*.

Riesman Memorial Lecture.—The Women's Medical Society of the University of Pennsylvania sponsored the Riesman Memorial Lecture at the University Hospital, May 1. The lecturer was Dr. Sara Murray Jordan, Boston, on "Problems in Modern Gastroenterology."

Haden Society Exhibit.—The Seymour Haden Society recently held its tenth annual exhibition at the University of Pennsylvania School of Medicine. Among the exhibitors were Drs. Isolde T. Zeckwer, Morton McCutcheon, Dale R. Coman and William G. Turnbull. The society was founded by Dr. Edward B. Krumbhaar, professor of pathology. At first the exhibitors were six members of the department of pathology; now members of other departments in the medical school and Philadelphia physicians not connected with the university participate. Originally etchings predominated in the exhibits, but this year oils and sculpture were most numerous.

Lectures on Genetics.—A volunteer lecture course on "Applied Medicogenetics" has recently been presented at the Woman's Medical College of Pennsylvania on Fridays. Clyde E. Keeler, Sc.D., fellow of the Wistar Institute of Anatomy and Biology, University of Pennsylvania, gave the first four addresses and later speakers were:

- Charles B. Davenport, Ph.D., Cold Spring Harbor, N. Y., Development of the Eugenic Movement.
- Dr. Elizabeth Kirk Rose, Philadelphia, Problems of Marriage and the Family as Met by the Physician.
- Dr. Madge T. Macklin, London, Ont., Case Histories from the Medicogenetic Consultation Room.
- Frederick Osborn, New York, A Permanent Eugenic Program for the United States.

TEXAS

Personal.—Dr. Sidney B. Hardy, who has been acting administrator of the Jefferson Davis Hospital, Houston, since the resignation of Dr. James H. Stephenson last year, has been appointed superintendent.—Dr. Charles H. McCollum Jr., Fort Worth, recently received the annual distinguished service award of the Fort Worth Junior Chamber of Commerce.

Chemist Honored for Vitamin Research.—Roger J. Williams, Ph.D., professor of chemistry at the University of Texas, Austin, received the \$1,000 Mead Johnson and Company prize awarded at the annual meeting of the American Institute of Nutrition in Chicago in April. Dr. Williams was honored "for his outstanding work on the isolation and identification of pantothenic acid." The prize is given for work on the vitamin B complex. Dr. Williams took his doctorate at the University of Chicago in 1919 and has taught chemistry at the University of Oregon and Oregon State College.

Society News.—Drs. Robert R. Shaw and Stuart A. Wallace, among others, addressed the Dallas County Medical Society, Dallas, April 24, on "Pulmonary Lobectomy and Pneumonectomy for Suppurative and Malignant Disease of the Lungs" and "Early Degenerative Lesions of the Pancreas" respectively. Drs. Charles L. Martin and Harry M. Spence, Dallas, were among the speakers, April 10, on "New Radiation Technic for Treatment of Metastatic Cervical Lymph Nodes" and "Surgical Treatment of Ureteral Stones" respectively.—Dr. Titus H. Harris, Galveston, addressed the Jefferson County Medical Society, Beaumont, April 14, on management of the nervous patient.

VIRGINIA

Personal.—Dr. Lee Scott Barksdale has resigned as health officer of Hopewell to enter private practice.—Dr. Guy C. Richardson, Bristol, recently received the distinguished service medal awarded annually by the Bristol Junior Chamber of Commerce to a citizen who has rendered noteworthy community service.—Dr. Julian T. Miller has resigned as health officer of Portsmouth.

Medical College News.—A bronze tablet commemorating the service of Base Hospital No. 45, known as the McGuire Unit, in France during World War I was recently presented to the Medical College of Virginia by the Base Hospital No. 45 Veterans' Association. Dr. William Lowndes

Peple, Richmond, made the presentation on behalf of Dr. Stuart McGuire, Richmond, commander of the unit, who was ill, to William T. Sanger, L.H.D., president of the college. The tablet was unveiled by Lockhart Bemiss McGuire, a great-nephew of Dr. McGuire.

State Health Officials Promoted.—Dr. Adrian L. Carson Jr., acting head of the bureau of maternal and child health in the state department of health since the retirement of Dr. Bathurst B. Bagby in July 1940, has been made full director of that bureau, it is reported. Previously he was a member of the staff. Dr. Jack B. Porterfield, who has been state epidemiologist, has been appointed director of the bureau of industrial hygiene. He succeeds Dr. William D. Tillson, now of Parkersburg, W. Va., who resigned several months ago. Dr. Harry H. Henderson, Wheeling, W. Va., has been appointed state epidemiologist to succeed Dr. Porterfield.

GENERAL

Medical Books in the Census of Manufactures.—Books on medicine published in 1939 amounted to 1,868,892 volumes, according to the biennial census of manufactures conducted by the U. S. Bureau of the Census. The annual average since 1925 has been 1,725,000 volumes. The biggest year was 1937, when 3,923,532 volumes were published. The total number of all books published in 1939 was 180,142,492.

Meeting of Radiologists.—The American College of Radiology will hold its annual meeting at the Hotel Statler, Cleveland, June 4. Dr. Henry J. Walton, Baltimore, will deliver his presidential address at the banquet, following the business session. A feature of the banquet this year will be the presentation of the medal for distinguished contributions to radiology to Dr. William Edward Chamberlain, Philadelphia.

Meeting of Postgraduate Committees.—The fifth annual meeting of the Associated State Postgraduate Committees will be held, June 4, at the Hotel Statler, Cleveland. Discussion will be centered on the relation of postgraduate committees to intern instruction in nonteaching hospitals and the possible cooperation in such instruction by members of other organizations. A report on the question of national registry of postgraduate assemblies and a registry for postgraduate instructors will also be presented.

Eradication of Brucellosis.—Forty-five additional counties in thirteen states were declared practically free from brucellosis of cattle, April 1, by the U. S. Department of Agriculture. Counties now in the modified accredited status number three hundred and ninety-one in twenty-three states, the department announced. In the forty-five new counties approximately 533,000 cattle were tested. The greatest number, about 69,500, were in Polk County, Minn.

American Orthopaedic Association.—The annual meeting of the American Orthopaedic Association will be at the Hart House, University of Toronto, June 9-12, under the presidency of Dr. David E. Robertson, Toronto. Included among the speakers will be:

- Dr. Frederick R. Wilkinson, Toronto, Osteomyelitis, Recent Experience with Bacteriostatic Drugs.
- Dr. Stuart A. Thomson, Toronto, Treatment of Club Feet by the Use of Dennis Brown Splints.
- Dr. Joseph S. Barr, Boston, End Result Study of the Treatment of Idiopathic Scoliosis.
- Dr. LeRoy C. Abbott, San Francisco, Valgus Deformity of the Knee Resulting from Injury to the Lower Femoral Epiphysis.
- Dr. Halford Haddock, New York, Surgical Stabilization of Paralytic Dislocated Hips.
- Dr. Robert W. Johnson Jr., Baltimore, Treatment of Acute Osteomyelitis by the Sulfathiazole Drugs.
- Drs. Lloyd T. Brown and John G. Kuhns, Boston, Extension Deformities of the Cervical Spine.
- Dr. Dallas B. Phemister, Chicago, Resection and Transplantation in the Treatment of Bone Sarcomas.

Painting on Yellow Fever Subject to Be Unveiled.—A painting by Dean Cornwell, the third in the series "Pioneers of American Medicine," will be unveiled during special ceremonies in the Hotel Statler, Cleveland, June 2. The painting shows Major Walter Reed and Dr. Carlos Finlay with Major General Leonard Wood, Dr. Jesse W. Lazear, Dr. James Carroll and Dr. Aristides Agramonte, and John R. Kissinger, first volunteer soldier to be inoculated in the second set of yellow fever experiments. Miss Blossom Reed, daughter of Major Walter Reed, will unveil the painting. Mr. Cornwell chose the yellow fever subject at this time because of its significance in connection with national defense, since the Panama Canal would have been impossible without the success of Finlay and Reed. The series of paintings, depicting outstanding personalities and events in the history of American medicine, will take between ten and fifteen years to complete, one painting

being done a year. Finished paintings are lent to medical schools and medical societies. The first two were "Beaumont and St. Martin" and "Osler at Old Blockley."

Ear, Nose and Throat Meeting.—The American Laryngological, Rhinological and Otolological Society will hold its forty-seventh annual meeting at the Ambassador Hotel, Los Angeles, June 16-18, under the presidency of Dr. John MacKenzie Brown, Los Angeles. Speakers will include:

- Drs. Fred Z. Havens and Edith M. Parkhill, Rochester, Minn., Malignant Tumors of the Larynx Other Than Squamous Cell Epitheliomas.
- Dr. Arthur C. Jones, Boise, Idaho, Report of Carcinoma in the Larynx in a Girl Aged Thirteen.
- Dr. Bert E. Hempstead, Rochester, Minn., Treatment and Prognosis of Aural Infections Complicated by Severe Diabetes.
- Dr. James Milton Robb, Detroit, A Consideration of the Endocrine Basis for Otosclerosis (candidate's thesis).
- Dr. Robert C. Martin, San Francisco, Result of Extirpation of the Sphenopalatine Ganglion.
- Dr. Herbert Graebner, New York, Chemotherapy in Acute Nondiphtheritic Laryngotracheobronchitis.
- Dr. Emil F. Tholen, Los Angeles, Salivary Calculi.
- Dr. Kenneth M. Day, Pittsburgh, Primary Pseudocholesteatomas of the Ear.
- Dr. Gabriel Tucker, Philadelphia, Observations on the Interrelationship, Diagnosis and Treatment of Benign and Malignant Tumors of the Larynx, with Special Reference to the Prevention and Cure of Laryngeal Cancer.

Directory of Medical Specialists.—A second edition of the Directory of Medical Specialists has been authorized by the Advisory Board for Medical Specialties, to be ready for distribution in February 1942, with its contents complete to January 1. This directory is the official publication of the board and will list the names of approximately 18,000 diplomates of the fifteen American boards examining candidates for certification in the specialties. This is an increase of 4,000 over the first edition issued early in 1940. The geographic grouping will give completely revised biographic data about each diplomate; there is an alphabetical index with addresses and specialty designations, and the plan of organization, officers and examination requirements of each American board are fully outlined. Information not found in the old edition will be included in the new directory, such as details of formal training and military appointments. The only requisite to inclusion in the directory is formal certification by one of the examining boards. The publication is issued through the Columbia University Press of New York. The secretary of each specialty board serves on the Advisory Editorial Board and Dr. Paul Titus, 1015 Highland Building, Pittsburgh, of the American Board of Obstetrics and Gynecology is the directing editor.

Association for Study of Allergy.—The nineteenth annual meeting of the American Association for the Study of Allergy will be held at the Hotel Cleveland, Cleveland, June 2-3, under the presidency of Dr. Robert L. Benson, Portland, Ore., who will deliver his address Monday on "The Place of Allergy in Internal Medicine." The speakers will include:

- Drs. Samuel J. Levin, and Bertha Lillian Shulsky, Detroit, Serological Changes after Oral Ragweed Pollen Therapy in Children.
- Oren C. Durham, North Chicago, Ill., A Critical Interpretation of Data on the Incidence of Air-Borne Allergens.
- Drs. John M. Sheldon, John Harvey Johnston and Homer A. Howes and Norbert Fell, Ph.D., Ann Arbor, Mich., A Clinical Study of Histamine-Azo-Protein in Allergic Disease.
- Dr. Townsend B. Friedman, Dr. John A. Bigler and Marie A. Werner, Chicago, The Immunologic Response of Allergic Children to Toxoid.
- Dr. George F. Harsh and Paul B. Donovan, Ph.D., San Diego, Calif., Effect of Wide Variations in K and Na Intake in Asthmatic Patients.

A round table discussion will be held Tuesday afternoon on the use and misuse of drugs. In this group Drs. George Pinness, Los Angeles, and Warren T. Vaughan, Richmond, Va., discussing self-administered medication, will present, respectively, "Inhalation of Adrenalin and Benzedrine" and "Ephedrine and Synthetic Derivatives." Dr. Philip D. McMaster of the Rockefeller Institute for Medical Research, New York, has chosen for his subject as the banquet speaker "The Lymphatic Participation in Human Cutaneous Phenomena."

Health Contest Winners Announced.—Winning cities in the twelfth annual health contest conducted by the U. S. Chamber of Commerce in cooperation with the American Public Health Association and with the financial support of the Metropolitan Life Insurance Company were as follows: Baltimore; Evanston, Ill.; Greenwich, Conn.; Hackensack, N. J.; Hartford, Conn.; Honolulu, Hawaii; Madison, Wis.; Memphis, Tenn.; Newton, Mass.; and Pasadena, Calif. Winners in the seventh annual rural health contest were the following, chosen from three hundred and thirteen rural health units enrolled: Alcona-Ogemaw-Iosco-Oscoda counties and Alger-Schoolcraft counties in Michigan; Arlington County, Va.; Davidson County, Tenn.; Fayette County, Ky.; Forsyth County, N. C.; Coahoma County, Pike County and Lauderdale County, Miss.; Pickens County, Ala.; El Paso County and Tyler-Smith counties, Texas;

Thurston County, Wash., and Wasco County, Ore. The rural health contests are financed by the W. K. Kellogg Foundation of Battle Creek, Mich. In addition, special contests were held for noteworthy achievement in tuberculosis and syphilis control programs. Hartford, Conn., and Newton, Mass., won the contest for the most effective tuberculosis control programs, and the winners for the most effective syphilis control programs were Louisville, Ky.; Chicago; Memphis, Tenn., and Pasadena, Calif.

American Radium Society.—The twenty-sixth annual meeting of the American Radium Society will be held at the Hotel Cleveland, Cleveland, June 2-3, under the presidency of Dr. Frederick W. O'Brien, Boston. Speakers will include:

- Drs. John V. Blady and William Edward Chamberlain, Philadelphia, Five Year End Results in Intrinsic and Extrinsic Laryngeal Cancer.
- Drs. John E. Leach, Joseph H. Farrow, Frank W. Foote Jr., and Nestor William Wawro, New York, Fibrosis of the Lung Following X-Radiation for Breast Cancer.
- Dr. Shields Warren, Boston, Pathologic Aspects of Radiosensitivity of Malignant Tumors.
- L. D. Marinelli, M.A., New York, Dosage Determinations with Radioactive Isotopes.
- Helen Q. Woodard, Ph.D., and Dr. John M. Kenney, New York, Relation of Phosphatase Activity in Bone Tumors to the Deposition of Radioactive Phosphorus.
- Drs. Norman L. Higinbotham and Bradley L. Coley, New York, Effects of Preoperative Irradiation in the Treatment of Patients with Bone Sarcoma.
- Dr. Leroy Sante, St. Louis, Pneumoperitoneum as an Aid in Pelvic Irradiation.

The society will award the Janeway Medal to Dr. Edward H. Skinner, Kansas City, Mo., at the annual dinner Monday evening. Dr. Skinner will present the Janeway Lecture on "The Philosophy and Economics of Cancer." The Janeway lecturers are selected because of their outstanding scientific contributions.

Meeting of Broncho-Esophagological Association.—The twenty-fourth annual meeting of the American Broncho-Esophagological Association will be held at the Mid-Day Club, Cleveland, June 3, under the presidency of Dr. Gabriel Tucker, Philadelphia. Subjects to be discussed include:

- Dr. Carlos E. Pitkin, Cleveland, Repeated Severe Hemoptysis Necessitating Pulmonary Resection.
- Dr. Albert H. Andrews Jr., Chicago, Functional Examination of Respiration in Obstructive Diseases.
- Dr. Arthur E. Hammond, Detroit, An Intratracheal Tumor Causing Severe Attacks of Dyspnea.
- Dr. Maurice Bonnier, Montreal, Canada, Some Interesting Endoscopic Foreign Body Cases.
- Dr. Burt R. Shurly, Detroit, A Foreign Body Retained Thirteen Years in the Bronchus.
- Dr. George W. Grier, Pittsburgh, Mediastinal Enlargement in Acute

Dr. Surgical Treatment of Carcinoma of

- Dr. Herman J. Moersch, Rochester, Minn., Further Observations on the Treatment of Esophageal Varices by Injection of a Sclerosing Solution.
- Drs. Hugh G. Beatty and Dwight M. Palmer, Columbus, Ohio, Esophageal Neuroses.
- Dr. Edward B. Benedict, Boston, Carcinoma of the Esophagus with Special Reference to Treatment by Radical Surgery, X-Ray and Bougienage.
- Drs. Chevalier L. Jackson and Frank W. Konzelmann, Philadelphia, So-Called Adenoma of the Bronchus.
- Drs. Paul H. Holliger, Chicago, and Ralph G. Rigby, Council, Idaho, Bronchogenic Carcinoma Without Bronchial Obstruction.

Special Society Elections.—Dr. Jesse L. Bollman, Rochester, Minn., was elected president of the American Society for Experimental Pathology at its annual meeting in April; Dr. Baldwin H. E. W. Lucke, Philadelphia, vice president, and Dr. Harry P. Smith, Iowa City, secretary, reelected. Dr. Roscoe R. Graham, Toronto, was recently named president-elect of the Central Surgical Association at its inaugural meeting at the University of Michigan, Ann Arbor. Dr. Grover C. Penberthy, Detroit, was installed as president. Other officers include Drs. George M. Curtis, Columbus, Ohio, secretary; Henry K. Ransom, Ann Arbor, recorder; Max M. Zininger, Cincinnati, treasurer. The second meeting of the association will be held in Chicago, Feb. 27-28, 1942. The Central Surgical Association is designed particularly for a closer relationship of younger surgeons of the midwest and nearby Canadian provinces. Its principal founder was Dr. Roy D. McClure, Detroit, who was the first president of the group. The association was incorporated under the laws of Ohio, January 15. Its membership now totals one hundred and fifty members, including forty-seven founders, distributed over eleven states and three Canadian provinces. Dr. Samuel R. Haythorn, Pittsburgh, was elected president of the American Association of Pathologists and Bacteriologists at its annual meeting in New York, April 10. Other officers are Drs. Paul R. Cannon, Chicago, vice president; Howard T. Karsner, Cleveland, secretary, and Alan R. Moritz, Boston, treasurer. The next annual session will be held in St. Louis, April 2-3, 1942.

Invisible Dermatoses

In a recent paper before the Society of Dermatology, Gougerot justified the paradoxical use of the term "invisible dermatosis." He had in mind not so much cutaneous diseases which were invisible as those which exist in unperceived and attenuated form and are likely to become reactivated under changed conditions. This makes their early detection important. Wood's glass, infra-red photography, local leukoderma, pigmentation, ultraviolet irradiation, biopsy and local injections are among the diagnostic measures available. Invisible dermatoses are often associated with visible lesions. Their true nature is often disclosed under treatment and, like the original lesions, they yield to specific therapies. Pruritus, often observed in lichen planus as an isolated sign, can be cured by arsenic given internally and chrysophanic acid given externally. In eczema the harmful antigen induces an allergic pruritus. Some forms of dyshidrosis, urticaria and psoriasis reveal themselves in Wood's glass or by the use of eosin. Here the erythema of measles, scarlatina or syphilis is disclosed before it is seen with the eye. In leprids the injection of methylene blue stains the visible leprid at the same time that it discloses the presence of invisible maculae and is hence an excellent means for early diagnosis. Invisible pathologic phases have both a theoretical and a practical interest and open up questions of pathogenesis, early diagnosis, prognosis, therapy and prophylaxis, for example in eruptive fevers, and constitute one of the best tests of cure.

Procaine Hydrochloride in Disorders Involving the Cervical Sympathetic

According to Dos Ghallos, speaking before the Faculty of Medicine of Paris, the bronchopulmonary innervation is composed of a mass of terminal plexuses in the center of which are found the fibers of the vagus and two of the sympathetic. The lung is therefore a neurovascular organ. This is the reason why a therapeutic attack on the sympathetic seems indicated in many functional disorders of the lungs. In asthma, in the spasmodic cough of tuberculous persons, in bronchorrhoea and in the bronchopneumonia of nurslings remedial action by way of the sympathetic may be obtained through the use of procaine hydrochloride. In pulmonary embolism this drug may save life. In asthma, dyspnea and stubborn cough it may have to be used for a longer time and may serve for functional exploration. The effect aimed at is neither sympathicolytic nor vagolytic; it seems rather directed against the peripheral neurohormonal system and to involve, for the most part, a modification of secretory processes.

The author employed procaine hydrochloride in about 200 cases of adults and nurslings and encountered only five failures. Successful injections provoke the Claude Bernard-Horner syndrome and hyperemia in the corresponding superior member as well as in the superior portion of the neighboring thorax. If inadvertently the brachial plexus or the pleural dome has been injured by the needle, a painful cough results, which merely requires the injection to be postponed to the next day. The same is true if a blood vessel is injured; in this case blood will show in the syringe. Some other accidents may also follow drug intoxication. Dos Ghallos does not agree with other investigators who, like White, believe that a combination of alcohol with procaine hydrochloride gives more enduring results. On the contrary, he considers the combination unreliable, dangerous and needlessly painful. His technic is based on that of Leriche.

While recognizing the value of procedures which allow reaching the stellate ganglion and the thoracic chain in its upper portion, Dos Ghallos prefers the upper external route of Arnulf, which permits simultaneous infiltration of the stellate ganglion and of the first three or four thoracic ganglia. Procaine hydrochloride is best injected bilaterally in one or two sessions. It is repeated more or less often in accordance with clinical indications, generally two or three times a week. The only contraindications are cardiac insufficiency, which complicates respiratory disorders, pulmonary suppuration and acute pulmonary edema.

BRAZIL

March 31, 1941.

A New Antihemorrhagic Agent

Interesting work on snake venom has been done in São Paulo at the famous Butantan Institute. Among the properties of ophidian venom is the coagulating one described by Fontana in 1781. An application of this property for clinical purposes is being used according to the methods of Klobusitsky and König, who obtained the dissociation of the coagulating principles from the toxic ones of the venom. On this basis Eduardo Vaz and Anibal Pereira did experimental work at the Pinheiros Institute, employing a ferment extracted from the venom of species of the *Bothrops* type. It was demonstrated that the botropase is a therapeutic agent of great activity. Its coagulating effects are obtained by the use of small doses, of which the safe results are as satisfactory in rapidity as in duration. Several clinicians and surgeons confirmed the highly efficient action of the product. In view of this, botropase is widely used in Brazilian hospitals in all cases of hemorrhage. For an immediate effect, botropase can be injected intravenously in doses of 1 cc.; if there is danger of repetition of bleeding, 1 cc. should be injected subcutaneously at once. For prophylaxis a subcutaneous or intramuscular injection of 1 cc. should be given two to three hours before the surgical intervention.

Eduardo Vaz and Anibal Pereira read an article before the São Lucas Medical Society at São Paulo showing that the botropase is the best antihemorrhagic agent. Comparative experiments with other hemocoagulants proved that snake venom is superior, even when diluted 1:100 and used in a five times smaller volume than the others, which means five hundred times less.

The following conclusions were proposed:

1. By means of heating it is possible to separate the toxic from the hemocoagulant dose of the venom of *Bothrops jararaca*, thus allowing the use, devoid of danger, of a venom solution in the therapeutics of hemorrhages.
2. The heated solution, called botropase, does not alter the white corpuscles or the red ones, it shows no proteolytic properties in vitro and in vivo, and it does not cause local lesions or intoxications.
3. The hemocoagulating activity is extraordinary, 0.0002 cc. for the pigeon representing 0.0002 mg. of venom, which is a six thousand times smaller dose than the toxic one for this animal.
4. Botropase does not exhibit the negative phase which can be observed with other venom solutions.

Personal

The medical centers of São Paulo commemorated lately the professoral jubilee of Antonio Almeida Prado. All the medical societies held a solemn meeting, with the cooperation of the Faculty of Medicine and other official institutions. Professor Almeida Prado is well known by his works on mixed cerebellar syndromes and the publication of several medical books.

NEWS FROM GERMANY

(Compiled from recent German periodicals)

Matriculation of German Students

According to a decree, students of German origin within the conquered and annexed western provinces (Alsace, Lorraine and Luxembourg) are required to matriculate at certain designated universities. The explanation is that the difference in school systems under which the now repatriated students were taught does not fit in with the German pattern and requires the organization of introductory courses to prepare them for the German system. These introductory courses cannot be offered promiscuously. Hence Alsatian German students will matriculate in Frankfurt, Freiburg, Marburg and Tübingen; those from Lorraine in Heidelberg, Marburg and Leipzig, and those from Luxembourg in Bonn, Cologne, Giessen, Munich and Innsbruck. The decree will be effective until the beginning of the winter semester 1941-1942.

Medical Education in Alsace as Seen Through German Eyes

In the *Deutsche medizinische Wochenschrift*, Babillotte compares the medical training at the university of Strasbourg, conducted according to the French university system, with that of the vaunted German system. The Alsatian university pattern is considered as conforming in organization and spirit to the secondary school system, in which attendance and progress are constantly checked and intellectual independence is inhibited. The French-Alsatian system was characterized by numerous tests and competitive examinations. This made it difficult for students to transfer to other universities, as is customary in Germany. The writer concedes that the French-Alsatian system kept the students "on their toes" and tended to prevent the development of academic hoboos such as used to be plentiful on German university campuses.

In the university of Strasbourg the medical curriculum was fully planned and had to be followed. Electives did not exist. A premedical year was devoted to physics, chemistry, botany and zoology. Clinical studies were begun in the second year. The student might also apply for assignment as assistant during the second year. During the third year the student had to be assigned as an assistant in surgery or internal medicine. Obligatory assistantship continued also through the fourth year. Final examinations were given on all subjects. Pharmacology, medical jurisprudence, psychiatry, therapeutics, hydrology and hygiene were reserved for the fifth year. The assistant served his time during this year in the ear and eye or the children's clinics. Final examinations were divided into three parts. The doctoral dissertation was generally prepared several years after the completion of the finals. The dissertation constituted the official medical diploma. Its recording by the health department signified admission to medical practice.

Great importance was attached to these assistantships, only twenty of which were available annually. These were awarded after competitive examinations based on histology, physiology and clinical subjects. Those selected were called externs and assisted in the wards, laboratories and at operations. After spending two years as an extern the student was admitted to competitive examinations, which qualified him for the internship (equivalent to the position of assistant physician in the German system). The salary was 500 francs (25 reichsmarks) with free board and lodging. The internship lasted four years. At the end of the four years one was eligible, if there was a vacancy, for the position as head of a clinic, which was good for two years. Vacancies were filled by appointment by the director of the clinic.

The author points out other deficiencies inherent in French universities, such as the statement that no provision was made for sports, good fellowship or social and political activities. His comment, however, is focused on the "ridiculous" system

of competitive examinations. One gets the impression that one is listening to a spokesman of a superior nazi culture who has no understanding of the institutions of another people, intellectual though it may be, as are the French. It may be noted that Professor Leriche was for years head of the department of surgery of the university of Strasbourg. This university will now undergo a reform according to the nazi pattern.

Overcrowding in University of Oslo

Matriculation in the faculty of medicine of the University of Oslo has been such as to overtax lecture and training room facilities. Two hundred and sixty medical students, especially registrants for upper clinical courses, could not be accommodated. A number of German universities, such as Breslau, Leipzig, Freiburg and Erlangen, were opened to these students.

Smoking by Female Technicians

Smoking by female technicians is animadverted on in a recent article in the *Female Technical Assistant*. The increasing use of tobacco with exposure to possible damage due to nicotine, it is pointed out, does not represent cooperation with the objectives for which the medical profession and the health authorities are striving.

Police Order Regarding Abortifacients

A recent police order dealing with methods and means of preventing pregnancy and inducing abortion gives the authorities the power to proceed against those engaged in the manufacture, advertising and use of the most common abortifacients as well as against contraceptives detrimental to health.

Blood Donor Center

A blood donor center has been organized in the Auguste-Victoria Hospital in Berlin. Suitable blood donors may be obtained by telephonic inquiry. The charge for individual service is 3 reichsmarks.

Marriages

CLIFTON JENNINGS DERRICK to Miss Elizabeth Russell McKenzie, both of West Palm Beach, Fla., in February.

BERLIN FRANCIS BARHAM to Miss Nancy E. McNeely, both of Winston-Salem, N. C., at Cooleemee in February.

RICHARD C. WOODSON to Miss Catherine Wall, both of Birmingham, Ala., in St. Augustine, Fla., February 8.

JOHN WILLIAM THURMOND, Augusta, Ga., to Miss Dora Elisabeth Tarver in Aiken, S. C., in March.

HOWARD WALTER BAKER, Philadelphia, to Miss Anna Marie Springer of Phoenixville, Pa., February 22.

WILLIAM H. FRIZELL to Miss Margaret Alexander, both of Brookhaven, Miss., in Meridian, March 16.

BENJAMIN FRANKLIN LOUNSBURY to Miss Elizabeth Shuman, both of Oak Park, Ill., in March.

JOHN FRANCIS REGISTER to Miss Margaret Lucette Brewer, both of Greensboro, N. C., February 15.

ROBERT F. SLOTTERBECK, Toledo, Ohio, to Miss Gertrude Cole of Washington, D. C., March 3.

EDWIN LAWRENCE KENDIG JR., Richmond, Va., to Miss Emily Parker of Appalachia in March.

JAMES B. HICKS, Gadsden, Ala., to Miss Dagny Magnhild Everson of Elliott, Mo., in February.

DAVID R. WEILL JR., Chattanooga, Tenn., to Miss Eva Ada Winkler in New York, March 2.

ALSTON CALLAHAN, Vicksburg, Miss., to Miss Eivor Holst of San Francisco, February 23.

HAIG CARAPETIAN to Miss Letitia Ingram Belknap, both of New York, February 15.

AARON W. NEWTON to Miss Marie C. Benson, both of Cleveland, in March.

BENJAMIN J. STEVENSON, Sparta, Ill., to Miss Nora Phlegley of Modoc recently.

Deaths

Claude Thomas Wolfe • Louisville, Ky.; Kentucky School of Medicine, Louisville, 1907; clinical professor of ophthalmology at the University of Louisville School of Medicine; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during the World War; member of the staffs of the Norton Memorial Infirmary, Louisville City and Kentucky Baptist hospitals and St. Joseph Infirmary; consulting ophthalmologist at Kentucky School for the Blind; aged 57; died, April 9.

Jefferson Davis Bloom, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1886; professor of diseases of children during the years 1890, 1891 and 1892 at the New Orleans Polyclinic; fellow of the American College of Surgeons; consultant and honorary member of the staff of the Hotel Dieu, Sisters' Hospital; aged 79; died, March 21, of aspiration pneumonia and chronic myocarditis.

Denis Roscoe Wolff • Greensboro, N. C.; Jefferson Medical College of Philadelphia, 1918; fellow of the American College of Surgeons; served during the World War; on the staffs of St. Leo's Hospital, L. Richardson Memorial Hospital and Piedmont Memorial Hospital; aged 44; died, March 23, in St. Anthony Hospital, St. Petersburg, Fla., of regional ileitis.

Walter F. Enfield, Bedford, Pa.; Medico-Chirurgical College of Philadelphia, 1894; member of the Medical Society of the State of Pennsylvania; at one time president of the Bedford County Medical Society; in 1923 member of the House of Delegates of the American Medical Association; aged 69; died, April 11, of carcinoma of the pancreas.

Walter Herndon Nelson, Silverton, Colo.; University of Texas School of Medicine, Galveston, 1935; member of the Colorado State Medical Society; on the staff of the Mercy Hospital, Durango, from 1937 to 1939; aged 35; died, March 13, in the Colorado General Hospital, Denver, of coronary thrombosis and cerebral embolism.

Elisabeth A. Ryder, Devon, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1891; member of the Medical Society of the State of Pennsylvania; part owner and superintendent of the Alcluyd Hospital; aged 76; died, March 14, in the Bryn Mawr (Pa.) Hospital of hypertensive cardiovascular disease.

Arnold Edgar Robison • Provo, Utah; University of Nebraska College of Medicine, Omaha, 1921; past president and secretary of the Utah County Medical Society; served during the World War; formerly city physician; aged 46; on the staff of the Utah Valley Hospital, where he died, March 23.

Edwin Bannister Forbes • Detroit; Harvard Medical School, Boston, 1898; Medizinische Fakultät der Universität Wien, Austria, 1899; served during the World War; formerly county physician; aged 66; died, April 15, in the Harper Hospital of bronchopneumonia and carcinoma of the pharynx.

William O'Gorman Quinby • Newark, N. J.; Columbia University College of Physicians and Surgeons, New York, 1900; member of the American Academy of Ophthalmology and Otolaryngology; served during the World War; aged 64; died, March 24, of coronary occlusion and arteriosclerosis.

William Thomas McConville, Honesdale, Pa.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1895; member of the Medical Society of the State of New York; served during the World War; aged 69; died, March 18, in a hospital at Goshen, N. Y.

Llewellyn Powell, Alexandria, Va.; George Washington University School of Medicine, Washington, D. C., 1904; member of the Medical Society of Virginia; city coroner; served during the World War; on the consulting staff of the Alexandria Hospital; aged 62; died, March 13.

Henry John Heusinkveld • Fulton, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883; an Affiliate Fellow of the American Medical Association; for many years member of the board of education, and health officer; aged 81; died, March 13.

Thomas Wilson Crowder, Sherman, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1893; fellow of the American College of Surgeons; on the staff of St. Vincent's Hospital; aged 68; died, April 6, of gastric hemorrhage and heart disease.

Pearl Suvilla Waters, Patton, Calif.; Pulte Medical College, Cincinnati, 1910; member of the California Medical Association;

on the staff of the Patton State Hospital; aged 64; died, March 7, in St. Joseph Hospital, Orange, of carcinoma of the cervix.

Ernest Robertson • Beaumont, Texas; University of Texas School of Medicine, Galveston, 1925; served during the World War; aged 41; on the staffs of St. Therese Hospital and the Hotel Dieu Hospital, where he died, March 19, of cerebral hemorrhage.

John Horatio Dorsey, Grantsville, Md.; University of Maryland School of Medicine, Baltimore, 1885; veteran of the Spanish-American War; at one time a member of the state legislature of Minnesota; aged 89; died, April 10, of chronic myocarditis.

Edward Waddell Hooper, Humboldt, Kan.; Drake University Medical Department, Des Moines, Iowa, 1898; member of the Kansas Medical Society; served during the World War; aged 64; died, March 7, of carcinoma of the stomach and liver.

Albert Caleb Griffin, Whitestone, N. Y.; Albany Medical College, 1880; College of Physicians and Surgeons, medical department of Columbia College, New York, 1881; aged 85; died, February 20, of coronary thrombosis and arteriosclerosis.

Clifford Lombard Crittenden, Detroit; Michigan College of Medicine and Surgery, Detroit, 1905; aged 69; on the staffs of the Harper Hospital and the Grace Hospital, where he died, April 6, of bronchopneumonia and cirrhosis of the liver.

John Sherman Sprague, Indianapolis; Medical College of Indiana, Indianapolis, 1905; member of the Indiana State Medical Association; on the staff of the Veterans Administration Facility; aged 63; died, March 27, in St. Joseph Hospital.

Jonathan Arthur W. Burgess • Iowa Falls, Iowa; State University of Iowa College of Medicine, Iowa City, 1895; on the staff of the Ellsworth Municipal Hospital; aged 72; died, March 26, in Chicago of coronary thrombosis.

Marie Lois Grote, Topeka, Kan.; Northwestern University Woman's Medical School, Chicago, 1894; formerly on the staff of the Lincoln (Neb.) State Hospital; aged 79; died, February 17, of arteriosclerosis and bronchopneumonia.

Frank Hinkley, Brightwaters, N. Y.; Albany Medical College, 1898; member of the Medical Society of the State of New York; for many years on the staff of the Central Islip (N. Y.) State Hospital; aged 66; died, March 10.

Robert Hebenstreit, Buffalo; University of Buffalo School of Medicine, 1872; member of the Medical Society of the State of New York; aged 90; died, March 25, of bronchopneumonia and carcinoma of the bladder.

James Burrow Edwards, Fort Dodge, Kan.; Hospital College of Medicine, Louisville, Ky., 1898; member of the Kansas Medical Society; served during the World War; aged 73; died, April 4, of Parkinson's disease.

William Ashford Sampson, San Francisco; Hahnemann Medical College of the Pacific, San Francisco, 1909; served during the World War; aged 57; died, March 11, in the Veterans Administration Facility, Palo Alto.

Arthur Whitaker Belting • Trenton, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1903; formerly secretary of the state board of medical examiners; aged 62; died, March 24, of coronary thrombosis.

Harry Allen Sadden • Rochester, N. Y.; Syracuse University College of Medicine, 1908; served during the World War; on the staff of the Rochester General Hospital; aged 59; died, March 22, of acute leukemia.

George Peter Sackrider, Owosso, Mich.; Detroit College of Medicine, 1904; member of the Michigan State Medical Society; served during the World War; aged 66; died, March 11, of coronary occlusion.

Kenneth Earl Shaweker, Dover, Ohio; University and Bellevue Hospital Medical College, New York, 1914; fellow of the American College of Surgeons; served during the World War; aged 52; died, March 20.

Liselotte Herz, New York; Medizinische Fakultät der Universität Wien, Austria, 1938; intern at the Montefiore Hospital for Chronic Diseases; aged 26; died, March 18, of an overdose of sleeping tablets.

George Arthur Huntley, Branson, Mo.; University of Vermont College of Medicine, Burlington, 1897; for many years a medical missionary in China; aged 75; died, March 2, of myocarditis and influenza.

Adolph George Rave, Hicksville, N. Y.; Kentucky School of Medicine, Louisville, 1893; member of the Medical Society of the State of New York; aged 70; died, March 27, of arteriosclerosis and heart disease.

Eber Dunbar Kanaga, Palm Springs, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1908; member of the Washington State Medical Association; aged 63; died, March 31.

Ernest Choquette, St. Hilaire Village, Que., Canada; M.B., Laval University Faculty of Medicine, Quebec, 1884; M.D., Laval University Medical Faculty, Montreal, 1886; aged 78; died, March 29.

Fred Eli Redman, Washington, D. C.; Northwestern University Medical School, Chicago, 1907; served during the World War; on the staff of the Veterans Administration; aged 58; died, March 28.

John Lachlan MacIsaac, Antigonish, N. S., Canada; Baltimore Medical College, 1907; fellow of the American College of Surgeons; surgeon to St. Martha's Hospital; aged 71; died, March 25.

Ephym Efrem Syrkin, Brooklyn; Universität Bern Medizinische Fakultät, Switzerland, 1916; executive director of the Beth Moses Hospital; aged 52; died, March 26, of carcinoma of the larynx.

Oscar La Fayette Berdan, Strathroy, Ont., Canada; Trinity Medical College, Toronto, 1889; medical health officer of Strathroy; served during the World War; aged 72; died, March 3.

Harden T. Leach, Elston, Mo.; Washington University School of Medicine, 1896; member of the Missouri State Medical Association; aged 75; died, March 30, of arteriosclerosis.

Jesse M. Yonan, Chicago; Rush Medical College, Chicago, 1895; member of the Illinois State Medical Society; aged 73; died, March 13, of cerebral hemorrhage, arteriosclerosis and arthritis.

Harry Nalley, Mount Rainier, Md.; University of Maryland School of Medicine, Baltimore, 1900; member of the Medical and Chirurgical Faculty of Maryland; aged 64; died, February 7.

Israel Louis Feinberg, New York; University of the City of New York Medical Department, 1893; aged 70; died, April 13, in the Knickerbocker Hospital of cerebral hemorrhage.

James Walter Park, Kaufman, Texas; Louisville (Ky.) Medical College, 1880; member of the State Medical Association of Texas; aged 85; died, March 6, of coronary thrombosis.

Benjamin Franklin Babb, Ivor, Va.; University of Maryland School of Medicine, Baltimore, 1892; aged 76; died, March 31, in the Lakeview Hospital, Suffolk, of heart disease.

Abram M. Miller, Hyndman, Pa.; Baltimore Medical College, 1905; member of the Medical Society of the State of Pennsylvania; aged 71; died, March 4, of coronary thrombosis.

Thomas B. Perry, Miami, Fla.; College of Physicians and Surgeons, Baltimore, 1885; veteran of the Spanish-American War; aged 77; died, March 8, of acute dilatation of the heart.

William C. Watkins, Oconto, Wis.; Baltimore Medical College, 1905; member of the State Medical Society of Wisconsin; served during the World War; aged 61; died, March 19.

William H. Smith @ Cincinnati; Pulte Medical College, Cincinnati, 1896; on the staff of the Bethesda Hospital; aged 66; died, March 22, in Miami, Fla., of coronary thrombosis.

James Joseph Moorhead @ Terre Haute, Ind.; Rush Medical College, Chicago, 1895; on the staff of St. Anthony's Hospital; aged 78; died, March 16, of chronic myocarditis.

Archibald William Moss @ Binghamton, N. Y.; Long Island College Hospital, Brooklyn, 1921; aged 45; died, March 16, in Our Lady of Lourdes Hospital of cerebral embolism.

David Thomas Percy, Arlington, Mass.; Harvard Medical School, Boston, 1891; member of the New England Pediatric Society; aged 72; died, March 27, of coronary thrombosis.

John Robert Hendry, Detroit; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1922; aged 45; died, March 4, in the Harper Hospital of heart disease.

John Hunton Moss @ Binghamton, N. Y.; Jefferson Medical College of Philadelphia, 1914; served during the World War; aged 55; died, March 30, of coronary occlusion.

Rozilla Crofford, Burr Oak, Mich.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1886; Eclectic Medical Institute, Cincinnati, 1888; aged 80; died, March 31.

William Dalton Walker, Seattle; St. Louis University School of Medicine, 1903; aged 63; died, March 19, of pulmonary hemorrhage and dissecting aortic aneurysm.

James Taylor Walker, Richmond, Va.; College of Physicians and Surgeons, Baltimore, 1886; member of the Medical Society of Virginia; aged 81; died, March 12.

Robert Henry Montgomery, Detroit; Meharry Medical College, Nashville, Tenn., 1933; aged 34; died in March in the Grace Hospital of rheumatic heart disease.

John Henry Sullivan, Worcester, Mass.; Dartmouth Medical School, Hanover, N. H., 1894; aged 71; died, March 17, of arteriosclerosis and heart disease.

Stephen Summers Hanson, Haney, E. C., Canada; Western University Faculty of Medicine, London, Ont., 1893; aged 71; died, March 20, in Essondale.

John M. Fadeley, Point Pleasant, W. Va.; Maryland Medical College, Baltimore, 1905; county coroner; aged 63; died, April 10, of coronary thrombosis.

Richard Herrick @ Wyand, Ill.; Eclectic Medical Institute, Cincinnati, 1891; served during the World War; aged 76; died, March 25, of chronic myocarditis.

George C. Merriam @ Empire, Ala.; Atlanta (Ga.) College of Physicians and Surgeons, 1902; aged 66; died, March 22, in the Norwood Hospital, Birmingham.

Chauncey Wyckoff Howell @ Grinnell, Iowa; Northwestern University Medical School, Chicago, 1911; aged 54; died, March 10, of myocarditis.

George Alfred Hull, New York; New York Homeopathic Medical College and Hospital, New York, 1889; also a dentist; aged 71; died, March 18.

William Burchett Page, Granville, Tenn.; University of Nashville Medical Department, 1871; aged 90; died, March 7, of cerebral hemorrhage.

Carlyle Raymond Jones, Atlantic, Iowa; John A. Creighton Medical College, Omaha, 1908; aged 59; died, March 8, of pulmonary embolus.

Penrose Harold Marquette, Shamokin, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1925; aged 41; died, March 23.

Edgar Holm @ Eureka, Calif.; Northwestern University Medical School, Chicago, 1903; aged 63; died, March 9, of coronary embolism.

Franklin May Sanders, Adamsville, Tenn. (licensed in Tennessee in 1926); served during the World War; aged 53; died, March 16.

Charles Benjamin Abbott, Hillsboro, N. H.; Dartmouth Medical School, Hanover, 1902; aged 68; died, March 24, of heart disease.

Silas Grant Wertz, Wilkesburg, Pa.; Jefferson Medical College of Philadelphia, 1895; aged 72; died, March 18, in Pittsburgh.

Colin Reed Weirich, Bridgeville, Pa.; Jefferson Medical College of Philadelphia, 1882; aged 83; died, March 11, of lobar pneumonia.

Peter Radebaugh, Sturgis, Mich.; Miami Medical College, Cincinnati, 1887; aged 87; died, March 23, of influenza and prostatitis.

William S. Windsor, Climax Springs, Mo.; University of Maryland School of Medicine, Baltimore, 1890; aged 79; died, March 14.

George John Ott @ Boston; Albany (N. Y.) Medical College, 1894; aged 73; died, March 29, of a staphylococcal infection.

James Hutchinson Bartley, Zillah, Wash.; Rush Medical College, Chicago, 1900; aged 69; died, February 12, of heart disease.

Lee Zuber, Sweet Home, Ark.; University of Arkansas School of Medicine, Little Rock, 1901; aged 75; died, March 3.

William M. Houghton, Floydada, Texas (licensed in Texas, under the Act of 1907); aged 73; died in March.

George W. Sisler, Tulsa, Okla. (licensed in Oklahoma in 1924); aged 77; died, March 23, of coronary thrombosis.

Edgar Browning, Sherbrooke, Que., Canada; M.R.C.S., England and L.R.C.P., London, 1887; died, February 5.

William Y. Corry, Vancouver, B. C., Canada; Detroit College of Medicine, 1897; aged 72; died, February 16.

Harry E. Mechling, Louisville, Ky.; Hospital College of Medicine, Louisville, 1900; aged 71; died in March.

Harley Parker, Chicago; Hering Medical College, Chicago, 1895; aged 66; died, March 3.

Bureau of Investigation

KOCH CANCER "CURE" AND THE CANADIAN CANCER COMMISSION

THE JOURNAL has frequently commented on the Koch cancer treatment. The Bureau of Investigation is in receipt of a letter dated April 2 addressed to a physician in Texas, from the Koch Laboratories of Detroit, carrying the signature "Wm. F. Koch, Ph.D., M.D.," which reads as follows:

"The CANADIAN CANCER COMMISSION appointed by the ONTARIO Government has compiled a splendid series of scientific PROOFS of the EFFICACY of the KOCH TREATMENT in curing advanced CANCER.

"In order to make this presentation available to interested physicians it is reproduced verbatim in a four hundred page book which is distributed for one dollar to cover printing and mailing costs.

"To give a practical conception of the clinical and scientific aspects of this work our book on natural immunity will be sent to you for the asking.

"Aside from humanitarian interest you will find that these books offer you a means of increasing your efficiency and income."

Of interest in connection with the claim made in the first paragraph is a clipping taken from the *Toronto Daily Star* for March 19, which deals with a report of the Ontario Cancer Commission, pointing out that this is the third report and that it has nothing to add to its November report in which it expressed the opinion that the investigation of "Ensol," the discovery of Dr. Hendry Connell of Kingston, Ont., "be continued," that they would be willing to consider "Essiac," sponsored by Miss Rene Caisse of Bracebridge, "if furnished with formula and samples," and continues as follows:

"Or Glyoxylide, sponsored by Dr. David Arnott of London, Ont., the Commission reports it 'is still hopeful that progress may be made . . . And thinks it desirable to defer any review of the evidence before it to date or the expression of any opinion until it either has the benefit of some laboratory study or it is finally successful in having an investigation made.'"

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission, in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 added to the Food and Drug Administration's control of the advertising claims and statements made on the labels of medicines or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission, by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection, even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual, manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable.

Abstracts of some of the orders issued during 1940 follow:

Clito Products.—There are two of these, designated as "Clito Emmenagogue Capsules" and "Rayo De Sol" and put out by a Rene P. Balditt, trading as the Clito Company, San Antonio, Texas. The Federal Trade Commission's investigation revealed that Rayo De Sol is not, as represented, a cure for cataracts, cloudy vision, film cataracts, ulcers and inflammation of the eyes, and that Clito Emmenagogue Capsules are not a safe and competent treatment for delayed menstruation. On Oct. 28, 1940, the Commission ordered Balditt to cease making these misrepresentations and to discontinue advertisements that fail to reveal that Clito Emmenagogue Capsules may cause gastro-intestinal disturbances and excessive congestion and hemorrhage of the pelvic organs and, in case of pregnancy, may cause uterine infection and blood poisoning.

Concentra.—A Chicago concern operating under the name Jean Ferrell, Inc., advertised this product as a highly concentrated food, safe for use and (with the addition of liquids) as constituting a balanced diet capable of replacing the ordinary diet. It was also claimed to supply deficiencies of the body, to correct overweight and underweight and to eliminate poisons from the kidneys because of its gravel root content, and poisons in general from the body by action of its rhubarb content. The Federal Trade Commission on March 15, 1940, ordered the concern to discontinue these representations, charging that they were exaggerated and untrue, that the preparation is not a food and that because of its high content of rhubarb, it is a drug and not safe to use. Jean Ferrell, Inc., was also ordered to cease disseminating advertisements of Concentra which fail to reveal that continued use of the preparation over a long period would cause excessive purgation and result in serious injury to the health of the user. Another federal agency, the Food and Drug Administration, prosecuted Jean Ferrell, Inc., for misrepresentation on the ground that the claims made in or on the trade package of Concentra violated the Food and Drugs Act in fraudulently representing, among other things, that this nostrum was a food, whereas it consisted essentially of a drug. This drug was reported by government chemists to be rhubarb root. Their analysis also disclosed the presence of some dried extractive material, soya bean tissues and Irish moss tissues. This case, designated as *Notice of Judgment 30606*, November 1939, was reported in THE JOURNAL, May 4, 1940, page 1825.

Dermagell.—This product, originally put out by Research Associates, Inc., Washington, D. C., was later taken over by Dermagell, Inc., of the same city. It was claimed to be "a 3-purpose Cleansing Cream and Shampoo—so efficient—so utterly different from anything heretofore obtainable that authorities proclaim it 'the discovery of the century' . . . soothes and heals as it penetrates innermost recesses of the tender pores without unpleasant reaction . . . actually protects your skin . . . prevents and cures many skin disorders." The Federal Trade Commission, on May 16, 1940, declared that this product is not substantially different from any other preparations or soaps designed for similar use, that it possesses no special soothing or healing properties and that other claims made for it were false and misleading. It therefore ordered that such misrepresentations be discontinued in the advertising.

Faid.—This item is put out by the Chapman Health Products Company of Cleveland, which also put out "N. A. R. Tablets." The tablets were represented as a cure or remedy for rheumatism, neuritis and arthritis, and "Faid," also known as "Daintee," as a cure or remedy and a safe, scientific treatment for obesity. The latter, according to the Federal Trade Commission, contained powdered extract of phytolacca berries, sodium borate, berberine hydrochloride, apocynoid (?) and desiccated thyroid, in quantities sufficient to cause serious and irreparable injury to health if taken under customary and usual conditions or under those prescribed in the advertising. The composition of the N. A. R. Tablets was not given. The Federal Trade Commission, on May 10, 1940, declared that the representations made for these two products were unwarranted and ordered them discontinued.

Grape Cure for Cancer.—This treatment was exploited by one Johanna Brandt in her book "The Grape Cure," distributed by a Jessie F. Springer, operating as the Harmony Centre of New York. The Federal Trade Commission objected to this book on the ground that it represented that Johanna Brandt had cured herself of cancer through the use of the system of treatment described therein, which is based on the use of grapes, and that this treatment would cure cancer and practically all other human afflictions. The advertising itself contained objectionable representations, such as that most diseases originate in the intestine and are caused by poisons due to uneliminated waste; that grapes dissolve mucus, that those who develop malignant growths have in most cases been suffering from constipation; that salt, inorganic drugs and "patent medicines" cause cancer and that the system or method of treatment outlined in the book will restore one's health. On March 15, 1940, the Commission ordered that such misrepresentations be discontinued. The American Medical Association's records indicate that back in 1928 Johanna Brandt, who claimed to have come from South Africa the previous year, was herself running the Harmony Healing Centre in New York, which concern was charged by state officials with practicing medicine without a license. Soon afterward one F. W. Collins, calling himself "dean" of the First National University of Naturopathy, Newark, N. J., announced that his institution had become the headquarters of the "Centre." Evidently the concern later was reopened in New York by Jessie Springer. It capitalized on the "grape cure" propaganda by advertising that it had grape juices and grape concentrates for sale, as well as various "health books." The authors of some of these books were readily recognized as quacks or food faddists.

Nu-Myst.—This nostrum, put out by the Forson Laboratories, Inc., New York, was described by the Federal Trade Commission as "a liquid composed of common ingredients prescribed by physicians for relieving 'colds,' and containing menthol, camphor, thymol, oil of pine, eucalyptol, benzyl benzoate and aromatics, with an alcohol base of 87 per cent." The Commission charged that the Forson concern—through radio broadcasts and newspaper and magazine advertisements—falsely represented that its product would bring speedy relief to sufferers from colds, hay fever, rose fever, asthma and other nasal and bronchial disorders. The Commission pointed out that the disorders named, except colds, are grouped under the so-called allergies, the causes of which are manifold, and since there are so many causes it is impossible for a formula such as "Nu-Myst" to bring relief from any of these conditions. On April 14, 1940, therefore, the Commission ordered the Forson people to cease and desist from representing that their preparation will destroy or prevent the growth of bacteria; that it is a cure or remedy for colds, whooping cough, hay fever, rose fever or asthma or that it is an effective treatment for relief of these ailments beyond such temporary relief as may be afforded by the temporary allaying of local irritation.

COMING EXAMINATIONS

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, May 24, page 2425.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, June 23-25. Part III. Various centers, June or July. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written. Part I. Various centers, Nov. 1. Final date for filing application is Aug. 4. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York City.*
AMERICAN BOARD OF DERMATOLOGY AND SYPHILIGOLOGY: *Written. Nov. 3. Final date for filing application is Sept. 23. Oral. Dec. 12-13. Final date for filing application is Nov. 8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.*
AMERICAN BOARD OF INTERNAL MEDICINE: *Oral. June, in advance of the meeting of the American Medical Association. Written. Oct. 20. Final date for filing application is Sept. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.*
AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral. Philadelphia, June 6-7. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville, Ky.*
AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written. Part I. or June. Final date for filing application is 90 days in advance of the examination. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.*
AMERICAN BOARD OF OPHTHALMOLOGY: *Oral. New York, June 2; Portland, July 15; Chicago, Oct. 18. Written. March 7, 1942. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.*
AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Washington, January. Final date for filing application is Nov. 1. Sec., Dr. Guy A. Caldwell, 1640 State St., New Orleans, La.*
AMERICAN BOARD OF OTOLARYNGOLOGY: *Chicago, Oct. 16-18. Final date for filing application is July 1. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.*
AMERICAN BOARD OF PEDIATRICS: *Oral. Boston, Oct. 7-8, immediately following the annual meeting of the American Academy of Pediatrics. Written. Locally, Aug. 22. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.*
AMERICAN BOARD OF RADIOLOGY: *Oral. All groups. Cincinnati, Sept. 19-21. Final date for filing application is Aug. 1. Sec., Dr. Byrl R. Kirklind, 102-110 Second Ave., S. W., Rochester, Minn.*
AMERICAN BOARD OF UROLOGY: *Chicago, February. Final date for filing application is three months before date of examination. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.*

Pennsylvania January Report

The Pennsylvania State Board of Medical Examiners reports the written and practical examination for medical licensure held at Philadelphia, Jan. 7-11, 1941. The examination covered 5 subjects and included 50 questions. An average of 75 per cent was required to pass. Forty-nine candidates were examined, 47 of whom passed and 2 failed. Six physicians were licensed by reciprocity and 1 physician so licensed by endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

LICENSED BY ENDORSEMENT

Arizona January Report

The Arizona State Board of Medical Examiners reports the written examination for medical licensure held at Phoenix, Jan. 7-8, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. One candidate was examined and passed. One physician was licensed to practice medicine by reciprocity and 1 physician so licensed by endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

MEDICOLEGAL ABSTRACTS

Malpractice: Osteomyelitis Attributed to Force Used by Physician in Restraining Patient.—As the patient, a boy of 7 or 8 years of age, was being wheeled into the operating room preparatory to the removal of his adenoids by the defendant physician he became frightened and kicked a nurse in the stomach. The physician seized him by his arms and held him down on a table until the nurse administered ether. The following day finger marks were visible on the boy's skin at the upper end of the right humerus. About five days after the operation the child began to suffer from osteomyelitis of the upper right humerus. Attributing the osteomyelitis to the physician's grasping of the child's arm in the operating room, two suits were instituted against the physician, one by the child's father and the other on behalf of the child. The two suits were apparently consolidated for trial.

At the trial medical experts, apparently called by the physician, testified that although trauma with the presence of an infectious germ is an adequate cause for osteomyelitis, the source of osteomyelitis in the minor must be sought in some occurrence prior to the date of the operation, by which time the trouble was already in the process of development. To controvert this testimony, the plaintiffs called a general practitioner of medicine who, according to his testimony, in thirty-one years of practice had treated more than a hundred patients with osteomyelitis. This physician testified that "trauma with the presence of an infectious organism in the system would be an adequate cause of osteomyelitis at the place of the trauma; and that the grasping of the boy's arm and forcing him down upon a table with sufficient force to leave finger marks would be adequate cause for the 'stretching of the capsule in the boy's arm at the glenoid fossa,' which condition was indicated in a roentgenogram that had been taken of the child. The court then refused to permit the witness to answer three hypothetical questions, one of which, in effect, would have called for his opinion as to whether or not the grasping of the boy's arms in the operating room was an adequate cause of the osteomyelitis;

another as to what caused the osteomyelitis; and the third as to whether a force sufficient to leave marks on the arm would, if there was some stretching of the capsule, be sufficient to cause osteomyelitis. From verdicts in favor of the physician the plaintiffs, in effect, appealed to the Supreme Judicial Court of Massachusetts, Worcester, claiming the trial court erred in refusing to permit the witness to answer the questions referred to.

The testimony of the witness called by the plaintiffs as an expert that was permitted in evidence, said the Supreme Judicial Court, made plain to the jury that the violent grasping of the boy's arms under the circumstances might produce osteomyelitis. It was not error for the trial court to exclude the opinion of the witness as to whether the osteomyelitis existing five days after the operation was or could be so caused. In his discretion the trial court might decide that the physician in question was not sufficiently versed in osteomyelitis to make his opinion valuable to the jury since the qualifications of an expert are to be determined by the trial judge, and his judgment is seldom overturned. The verdicts of the jury in favor of the defendant were not, in the opinion of the court, tainted by any error of law and were accordingly affirmed.—*Carboneau v. Lachance* (two cases), 29 N. E. (2d) 696 (Mass., 1940).

Malpractice: Release of Hospital as Bar to Action Against Physician.—The plaintiff's wife died, allegedly, from an overdose of paraldehyde, a narcotic administered for the purpose of producing "twilight sleep." The defendant, the attending physician, had prescribed the administration of 4 drachms (15 cc.) of the drug, but a nurse employed by the hospital gave the patient 4 ounces (120 cc.) instead. The plaintiff eventually made a settlement, in the amount of \$1,900, with the hospital owner, the settlement being based on the theory that the death was due to the negligence of the nurse employed by the hospital. The plaintiff then sued the defendant physician for damages for the wrongful death of his wife. From a judgment for the defendant in the trial court, the plaintiff appealed to the Supreme Court of Florida.

The defendant contended that he and the hospital, if guilty at all, were guilty as joint tortfeasors and that the release of the hospital owner barred the plaintiff from any further claims on account of his wife's death. The Supreme Court said that the theory of the release was that the death was caused by the hospital owner or her servant, the nurse who actually administered the drug, and that the theory of the present lawsuit was that the defendant physician was solely responsible for the death because he negligently prescribed the use of the drug and caused it to be administered. These theories were so inconsistent, held the court, that there could not be a recovery on both of them. Whether the hospital owner and the attending physician were joint or several tortfeasors, continued the court, the law would not permit the plaintiff to treat them as several for the purpose of making a settlement with one, as was done here, and then treat them as joint for the purpose of an action at law against the other to recover for the same wrong. The judgment in favor of the defendant physician was therefore affirmed.—*Sands v. Wilson*, 191 So. 21 (Fla., 1939).

Workmen's Compensation Acts: Compensability of Diseases Contracted by Nurses and Interns.—In three cases which arose in New York, the question concerned the application of the workmen's compensation act to certain diseases contracted by nurses and interns in the course of their duties. In the *Miller* case, the plaintiff was a student nurse and became disabled as the result of tuberculosis alleged to have been contracted as a result of the nature of her employment. While the claimant was unable to name any particular patient suffering from tuberculosis whom she attended, the record disclosed that an examination made at the time she entered the service established that she had no symptoms of the disease. There was medical testimony to the effect, too, that the claimant became infected subsequent to her admission as a nurse. The supreme court, appellate division, third department, affirmed an award of compensation in favor of the nurse, but the Court of Appeals reversed the award and remanded

the case to the industrial board for a further hearing on the ground that the evidence was insufficient to sustain the award. In the *Waterman* case, the supreme court, appellate division, third department, affirmed an award in favor of a nurse who contracted syphilis while caring for an infant suffering from congenital syphilis. In the *Turitto* case, the plaintiff was an intern who lost the sight of one eye because of gonorrheal ophthalmia contracted while attending a patient suffering from acute gonorrheal urethritis on whom an operation had been performed. The supreme court, appellate division, third department, affirmed the award of the industrial board in favor of the plaintiff.—*Miller v. City of New York et al.*, 14 N. Y. S. (2d) 680 (N. Y., 1939), 26 N. E. (2d) 821 (N. Y., 1940); *Waterman v. Jamaica Hospital et al.*, 14 N. Y. S. (2d) 636 (N. Y., 1939); *Turitto v. St. Mary's Hospital et al.*, 14 N. Y. S. (2d) 647 (N. Y., 1939).

Dead Bodies: Disposal Must Not Offend Common Decency.—The aged sister of the equally aged defendant with whom she had lived died following a fall. The defendant dragged the corpse down into the basement, built up a roaring fire in the furnace and shoved it gradually into the flames. A neighbor noticed a heavy, dark smoke with a rather disagreeable odor pouring from the chimney of the defendant's house and reported that fact to the police. A police officer was later sent to the defendant's home to make an investigation. The defendant took the officer down into the basement, scraped the ashes out of the furnace and said "If you want to see her, there she is." Only a few bones were found. The defendant was subsequently convicted of indecently and unlawfully disposing of his sister's dead body "to the great indecency of Christian burial," and he appealed to the Supreme Judicial Court of Maine.

It was conceded that the defendant had not committed an offense covered by any specific statute, but the state contended that he was guilty of a crime at common law. Any disposal of a dead body, said the Supreme Judicial Court, which is contrary to common decency is a crime at common law. The court could not agree with the defendant's argument that, because cremation is now a well recognized method of disposing of dead bodies and is not contrary to common decency, the defendant's burning of the dead body of his sister was not a crime. As was stated in *Reg. v. Price*, 12 Q. B. D. 247, ". . . a person who burns instead of burying a dead body does not commit a criminal act, unless he does it in such a manner as to amount to a public nuisance at common law." In the present case the offense was not that the body had been burned but that it had been indecently burned "in such a manner that, when the facts should in the natural course of events become known, the feelings and natural sentiments of the public would be outraged." The judgment of conviction was therefore affirmed.—*State v. Bradbury*, 9 A. (2d) 657 (Maine, 1939).

Malpractice: Liability of Physician for Prenatal Injuries to Infant.—The plaintiff, a girl aged 11 years, by her mother as guardian ad litem brought suit against the defendant physician for injuries sustained by her prior to her birth. She claimed that, because of the alleged negligent application of "metal clamps and forceps" by the defendant to assist him in delivering her prior to her birth, her "brain cells and spine" had been seriously injured resulting in permanent paralysis. She based her right of action on section 29 of the Civil Code of California, which provides: "A child conceived, but not yet born, is to be deemed an existing person, so far as may be necessary for its interests in the event of its subsequent birth." The plaintiff's mother was not personally a party to the suit. The trial court upheld the defendant's demurrer and rendered judgment in his favor. The plaintiff then appealed to the district court of appeal, third district, California.

The district court could not agree with the defendant's contention that the word "interests," as used in the statute just quoted, is limited in its application to a child's right of inheritance or to its property rights and does not give the plaintiff the right to maintain an action for tort committed on her prior to her birth. The language of the statute, said the court, is as

clear and concise as the English language can make it, and there is nothing to indicate that the word "interests" is not used in its general sense of anything that is profitable or beneficial to the child. The court held, therefore, that the statute was broad enough to include both personal rights and property rights.

The defendant's further contention, that the statute should be construed to be merely a continuation of the common law with respect to the rights of an unborn child, likewise did not meet with the court's approval. At common law the great weight of authority does hold that an unborn child has no existence as a human being separate from its mother and that therefore it has no right of action for personal injuries inflicted on it prior to its birth by the wrongful act of another. But the California statute in question is diametrically opposed to that common law theory because it declares that under certain circumstances an unborn child shall be deemed "an existing person." Certainly such a radical change from the common law rule cannot be considered a continuation of such rule. Since this statute considers an unborn child an existing person, after its birth its parents, by authority of section 376 of the California Code of Civil Procedure, have the right to maintain an action in the child's behalf for injuries sustained by it through the wrongful act or neglect of another. Furthermore, even at common law a distinction has often been drawn between an unborn child whose lungs and other organs are fully developed, so that it would be capable of living separate and apart from its mother, and one which is less developed. The language of some of the court decisions indicate that an action might lie for injury to an unborn child if it were viable at the time of the injury. The court remarked that in the present case there was no doubt that the child was viable and capable of existence separate and apart from its mother at the time of the alleged injury. It was fully developed in every respect. The injuries were alleged to have occurred in the very process of delivering the child.

We do not suggest, said the court, that the defendant in the present case was guilty of malpractice. It may be true that he made no mistake in the delivery of the child. Even if he did, a mere mistake in the judgment of a physician does not constitute malpractice. It may be impossible for the plaintiff to prove satisfactorily that the defendant's conduct contributed in any degree to her unfortunate condition, but the mere fact that the assumed wrong is not readily susceptible of proof should not deprive the plaintiff of her right to pursue a remedy for that assumed wrong.

The district court, therefore, reversed the judgment for the defendant and directed the trial court to overrule the demurrer and permit the defendant to answer. On appeal by the defendant to the Supreme Court of California the opinion and judgment of the district court were affirmed.—*Scott v. McPheeters*, 92 P. (2d) 678; 93 P. (2d) 562 (Calif., 1939).

Dental Practice Acts: Revocation of License for Unlawful Advertising—When "Harsh and Unreasonable."

—The defendant state board of registration and examination in dentistry of New Jersey on Jan. 4, 1939 formally charged the plaintiff, a licensed dentist, with having advertised in the Jan. 19, 1938 issue of the *Jersey Journal* "the prices and charges to be made for dental work . . . as well as the character and durability of said work" in violation of a New Jersey statute which prohibits advertising by dentists. The evidence showed that this was the only violation which the plaintiff had committed. After a hearing on a plea of guilty by the plaintiff, the board formally adopted a resolution, on March 24, 1939, revoking the plaintiff's license to practice dentistry. From the board's ruling the plaintiff appealed to the supreme court of New Jersey.

A New Jersey statute, said the supreme court, provides:

The [supreme] court may reverse or affirm in whole or in part the finding or determination of the board or pronounce such judgment on the evidence as shall be warranted.

The court held that under this statute it had the right to review the board's action and pronounce such judgment as it saw fit. The plaintiff's only contention was that the ruling of the board should be reversed because the revocation of his license was too harsh and unreasonable a penalty. The board, on the other hand, contended that the penalty was justified

because the plaintiff had twice been put on notice of the illegality of the act which he subsequently performed. In 1935, the United States Supreme Court, in *Sculler v. Oregon State Board of Dental Examiners*, 294 U. S. 608, 55 S. Ct. 570, 79 L. Ed. 1086, upheld the constitutionality of a statute similar to that which the plaintiff violated. In 1937, the supreme court of New Jersey, in a case decided by it, specifically directed the attention of the dental profession to the United States Supreme Court's decision. The board argued, in effect, that in view of these decisions the plaintiff had been amply warned of the possible consequences of his conduct. The supreme court pointed out, however, that the particular New Jersey statute in question was not upheld by the New Jersey courts until October 1938, nine months after the plaintiff's acts, and that it was not until a year after the plaintiff's acts that the board commenced its proceedings against him. This delay indicated to the court that there must have been some doubt even in the minds of the members of the board as to the validity of the statute, although they too were aware of the prior decisions. The court also called attention to the fact that the evidence showed that the plaintiff had practiced dentistry for sixteen years and had enjoyed a good reputation in that profession. In view of that evidence, plus the fact that the defendant was guilty of but a single violation, and the additional fact that no other violator had been penalized greater than by a thirty day suspension of his license, the court concluded that the penalty fixed by the board was unreasonably harsh and severe. Accordingly, the order of revocation of the plaintiff's license was reversed and an order of six months suspension entered.—*Schwartz v. State Board of Registration and Examination in Dentistry*, 15 A. (2d) 322 (New Jersey, 1940).

Workmen's Compensation Acts: Chiropractic Adjustments as Medical Services.—The sole question before the Supreme Court of Michigan in this case was whether or not chiropractic adjustments constituted "medical services" within the meaning of the workmen's compensation act. In the opinion of the court they did. While a chiropractor is not permitted to use the term "doctor," "physician" or "surgeon," he is nevertheless in Michigan held to be engaged in the "practice of medicine," even though his practice covers only a very restricted part of the general field of that practice. The court reasoned that since chiropractic manipulation is within the meaning of "practice of medicine," it is also within the meaning of "medical services." In answer to arguments pointing out the dangers in compelling employees to submit to treatment from chiropractors rather than from licensed physicians, the court disavowed any intention of holding that employees could be compelled to accept chiropractic treatment.—*Green v. Rawlings et al.*, 287 N. W. 557 (Mich., 1939).

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Thirteenth Annual Meeting, Held in Chicago, Nov. 1 and 2, 1940

The President, DR. CHARLES A. DOAN, Columbus, Ohio,
in the Chair

(Concluded from page 2432)

Immune Response in Drug-Treated Patients with Pneumococcic Pneumonia

DRS. LUTHER L. TERRY, LAWRENCE D. THOMPSON and JOSEPH C. EDWARDS, St. Louis: This report embraces observations on the presence of agglutinins, mouse protective power and the polysaccharide cutaneous test in 77 patients treated with type specific serum and sulfapyridine; 36 patients treated with sulfapyridine and pneumococcus antigen; 14 patients treated with sulfapyridine alone, and 2 patients who entered the hospital after the crisis and consequently received no specific therapy. These 129 patients were distributed over types I, II, III, IV, V, VII and VIII; 112 of them recovered; 17 died. Observations are presented also on 4 cases of type XIV pneumonia in which only agglutinin studies and polysaccharide cutaneous tests were done as the type XIV pneumococcus is usually avirulent for mice.

Specific polysaccharide cutaneous tests were performed and specimens were secured for determination of agglutinins and mouse protective tests before therapy, three hours after serum therapy when serum was given, twenty-four hours after the beginning of any therapeutic measure and at two to five day intervals thereafter during hospital stay. The tests were also performed a short time before death on those patients who died.

Conclusions: 1. The type specific polysaccharide cutaneous test is a more reliable aid in prognosis than the mouse protective titer or the agglutinin concentration of the patient's serum, especially in those patients receiving adequate amounts of serum. 2. A limited number of observations indicated that the type specific polysaccharide cutaneous test is not passively transferred. 3. The combination of pneumococcus antigen with sulfapyridine resulted in a higher percentage of positive type specific polysaccharide cutaneous reactions, in more positive agglutinin reactions and in a higher mouse protective power than were observed in the limited number of cases (12) when sulfapyridine was used alone. 4. Patients with type III pneumonia are in a class distinct from others. The immune response as gaged by the tests in this study are not stimulated to the same degree as in other types of pneumonia. This may account in part for the lack of good response to drug therapy in many type III infections. 5. Death does occur in certain cases in spite of antibody response apparently adequate as far as can be determined by the observations indicated.

Solubility Studies on Acetylsulfapyridine

DR. A. C. CURTIS and SIDNEY S. SOBIN, PH.D., Ann Arbor, Mich.: From the consideration of acetylsulfapyridine solubilities, hematuria (which may presage a dangerous or even fatal com-

plication) during the course of sulfapyridine therapy should be both predictable and preventable. Sample urines and prepared solutions of varying μ n and specific gravity were tested for acetylsulfapyridine solubility. Roughly, the solubility increased with the specific gravity and the degree of alkalinity. The increase in solubility with increasing specific gravity may be in part related to concentration of urea.

Clinically, hematuria developing in patients receiving sulfapyridine at the University Hospital invariably occurred with limited fluid intake and a considerable prerenal deviation of fluid, insufficient alkali to produce an alkaline urine and a tendency toward acidosis consequent on self-imposed restrictions of food. More rigorous attention to urinary alkalinity by means of alkali administration, water balance and an adequate intake of food in patients with this type of therapy should be the rule.

Preliminary studies on acetylsulfathiazole show that its behavior is essentially like that of acetylsulfapyridine.

Influence of Sulfathiazole, Sulfapyridine and Sulfanilamide on Experimental Infections in Mice

DR. MERLIN L. COOPER and H. M. KELLER, M.S., Cincinnati: All mice survived when fed, ad libitum, a complete diet containing 1 per cent of sulfathiazole two or more days before being inoculated with *Shigella paradysenteriae* Flexner. Ninety-five per cent of mice survived a minimum fatal dose of *S. paradysenteriae* Flexner when different groups of mice were given, three hours later, a single dose of 1 mg. by stomach tube of sulfathiazole, sulfapyridine, sulfanilamide and sulfamethylthiazole. Seventy-eight per cent survived 10 minimum fatal doses, 38 per cent survived 100 and 3 per cent survived 1,000 minimum fatal doses. Similar results were obtained with *Shigella paradysenteriae* Sonne and *Shigella alkaesens*. Bacterial counts every three hours on the abdominal fluid and tail blood of infected mice showed that the counts in the untreated mice increased rapidly up to the time of death. In the mice treated with one dose of 2 mg. of sulfathiazole three hours after injection of the bacteria, the counts increased until six hours after administration of the drug, then rapidly decreased, and the mice recovered.

Changes with Age in Embryonic Heart Action as Recorded in Micromoving Pictures

BRADLEY M. PATTEN, PH.D., Ann Arbor, Mich.: The subject matter for this talk has been selected from a series of studies carried out on embryos kept alive with the aid of specially constructed glass chambers and artificial nutrient mediums. By this method it is possible to keep the living heart under continuous observation for long periods and to study the changes in its activities which accompany its structural development. Inherent local differences in the rate of contraction and the direction of propagation of beat were recorded by means of micromoving pictures. By the use of three stage amplification, records were obtained showing the sequential appearance of first, a simple sinusoidal curve, then the ventricular and later the sinoatrial complexes of the electrocardiogram. Electrocardiograms of adult pattern were obtained from the embryonic heart before its nervous connections had been established and before any of the so-called conduction system became recognizable microscopically.

Visualization of the Pulmonary Artery During Its Embolic Obstruction

DRS. JOSEPH H. JESSER and GEZA DE TAKATS, Chicago: With a 25 per cent solution of sodium iodide, two hundred and sixty-three exposures were made in 48 dogs in various positions and at various intervals. The pattern of the vascular tree was studied before and after the production of massive and peripheral types of emboli. In massive pulmonary embolism, with total obstruction of the main pulmonary artery, not only the right side of the heart but the inferior vena cava and the hepatic veins were seen to be engorged. In the peripheral type of embolism, obstructing the blood supply of one lobe or even less pulmonary tissue, arterial spasm was demonstrated in other areas. Areas of localized emphysema, indicating incomplete bronchial obstruction, were visualized. The effect of papaverine on the pulmonary vascular bed was studied. The clinical significance of these studies was noted.

DISCUSSION

DR. GEZA DE TAKATS, Chicago: It has been shown by post-mortem studies that patients will die an unexplained death with a small embolus in the lower lobes of the lungs without obstruction to the main artery. This is difficult to explain unless it is assumed that certain reflex changes originate from this embolus, either from the periphery or from the dilatation of the right side of the heart and particularly of the pulmonary artery itself. Pressor receptors have been shown to exist in the pulmonary artery. It is felt that if the pressure is raised in the pulmonary artery a depressor effect can be obtained in the systemic circulation. We have some experiments to show that a bronchial constriction occurs during pulmonary embolism which may be abolished by papaverine. This work shows that in addition to the bronchodilator effect of papaverine there is an effect on the vascular bed. On the basis of these studies we feel that the pulmonary vascular bed can constrict and dilate under nervous influence and that the effect of papaverine on the pulmonary embolism might be explained by the additional effect on the pulmonary vascular system. We are not convinced that papaverine is the optimal drug. We are hoping that a more potent and more effective vasodilator can be found.

DR. LOUIS N. KATZ, Chicago: Changes in caliber of the pulmonary tree demonstrated by Dr. Jesser's method may not be due to active dilatation of the pulmonary blood vessels but rather to a passive dilatation following increase in the intrapulmonary vascular pressure. Recently we have been studying the changes in blood pressure in the pulmonary arteries of unanesthetized dogs by use of a modification of the London cannula. With papaverine we found that pressure in the pulmonary artery goes up at the same time at which the systemic arterial pressure goes down. I wonder, therefore, whether the dilatation recorded by Jesser and de Takats may not be due to a passive phenomenon associated with an increase in pulmonary pressure. This is important in considering the use of papaverine in pulmonary embolism. It may be that the action of papaverine may be different when pulmonary embolism is present from what it is in the absence of embolism, particularly if a spasm of the remaining pulmonary vessels is produced by the embolus.

Induction of Puberal Changes in Young Women with Primary Amenorrhea

DRS. W. O. THOMPSON, S. G. TAYLOR III and PHEBE K. THOMPSON, Chicago: Observations have been made on the effect of various estrogenic materials in the treatment of young women who have not matured sexually and who present a syndrome corresponding to that observed in many eunuchoid males whose testes have not descended. In such women, large doses of estrogenic material produce (1) development of the secondary sexual characteristics of the female, including the growth of the external and internal genitalia, the development of the breasts, the growth of axillary and pubic hair and the onset of intermittent uterine bleeding resembling menstruation; (2) a moderate increase in body weight, most noticeable in the buttocks, thighs and hips, augmenting the feminine appearance; (3) an increase in muscular strength, bodily vigor and mental acumen and (4) an increase in sex consciousness with a corresponding change in emotional status.

DISCUSSION

DR. C. M. MACBRYDE, St. Louis: It is known that the use of large doses of estrogenic material in experimental animals leads to damage to the ovaries which may be more or less permanent. That thought should be kept in mind when we treat eunuchoid persons. Perhaps it would be wise to emphasize the point that an attempt should be made to see whether stimulating therapy is effective; perhaps we have all been too eager to give up the stimulating therapy too soon. Do the changes Dr. Thompson and his associates produced disappear after treatment is discontinued, and must patients with this condition be treated indefinitely with estrogenic material to maintain the results as shown?

DR. S. G. TAYLOR III, Chicago: During the administration of stilbestrol the nipples of one of these patients became black, and a dark line developed between the umbilicus and the lower part of the abdomen in the midline. The umbilicus became deep black. There has been a slight decrease in this pigmentation during the

past month despite the continuation of treatment. I wonder if any one has an explanation.

DR. W. O. THOMPSON, Chicago: Damage to the ovaries as the result of administration of large doses of estrogenic material has been demonstrated, I think, and there is, of course, in the male damage to the testes as the result of administration of testis hormone, which may be so pronounced that spermatogenesis is abolished. The damage to the testes appears to be temporary, and recovery takes place when treatment is discontinued. All the patients I have shown received gonadotropic material which has been ineffective. There unfortunately is no gonadotropic material prepared from the pituitary gland itself that is of much clinical value. While we may have made an occasional woman menstruate during the administration of certain pituitary preparations, by and large all of them are of little value at the present time. The gonadotropic material from the serum of the pregnant mare is also a great disappointment. The most effective gonadotropic material available is that prepared from the urine of pregnant women, but its value in the female is still undetermined. It is not always easy to decide when hypogonadism is primary and when it is secondary. One of our eunuchoid men with both testes high in the inguinal canal has recently shown descent of both testes and genital growth with chorionic gonadotropin. The women reported in this study did not respond to the gonadotropic materials available now. While estrogens may theoretically damage the ovary, the changes produced were so striking that their use seems not only justifiable but desirable in women with primary amenorrhea. I should agree that it is a good therapeutic principle in hypogonadism to try the effect of stimulation therapy first and resort to substitution therapy if it fails.

DR. ELMER L. SEVRINGHAUS, Madison, Wis.: I think Dr. Thompson has made some statements that are too broad in his closing remarks. In his experience the serum from pregnant mares has been disappointing, but we have had distinctly good results with this type of thing. Dr. MacBryde reported another difficulty—that there is a time factor. We know that adolescence takes time and that an artificially produced adolescence takes time. If cases can be carried to the point of pregnancy and delivery I think it shows something can be done. Several of our cases have been successful in this sense.

DR. W. O. THOMPSON, Chicago: I am not entirely in agreement with Dr. Sevringhaus about the value of pituitary gonadotropin. It is of some interest that our third patient, who showed such striking development of secondary sexual characteristics during the administration of estrogenic material, had been treated by Dr. Sevringhaus for a year with a pituitary preparation without any effect.

The Peroral Use of Methyl Testosterone in Testicular Deficiency

DRS. E. PERRY McCULLAGH and H. R. ROSSMILLER, Cleveland: The clinical effects of methyl testosterone following its oral administration are compared with those of testosterone propionate administered by injection. The study is based on 19 cases. The drug has been administered over periods varying from a few weeks to ten months. The patients treated include some with severe prepubertal hypogonadism, primary pituitary disease with secondary hypogonadism and functional impotence. The observations indicate that methyl testosterone given perorally has a strong androgenic activity in that it produces in persons with androgenic deficiency a definite increase in the size of the penis and prostate gland, a general increase in body hair and increase in sexual potency. There is a striking increase in energy and endurance and the development of the typical aggressiveness of the normal male. The doses used have varied from 25 to 300 mg. daily. A gain in body weight of approximately 10 to 20 pounds (4.5 to 9 Kg.) within three weeks of beginning the administration of the drug has been noted. This is shown to be associated with retention of sodium, chloride and nitrogen. Consistent elevations in the basal metabolic rate have been seen after relatively large doses. Such increases in basal metabolism have amounted to as much as 54 per cent. Basal metabolic rates as high as plus 38 per cent have not been associated with the clinical picture of hyperthyroidism. The rate of growth may be greatly aug-

mented by the use of methyl testosterone. In 1 instance we have seen the growth rate increase from levels of 1 inch (2.5 cm.) a year before the age of 19 to 5½ inches (14 cm.) a year over a ten month period during the use of the drug. Continued large doses may cause oligospermia, such as has been reported after the use of testosterone propionate. An interesting side effect has been the development of gynecomastia in several of the cases.

DISCUSSION

DR. M. A. BLANKENHORN, Cincinnati: Have the authors made a decision of what the total growth is going to be? Has the actual growth been increased or merely accelerated? Will there be a taller youth or will the youth have reached his height sooner in life?

DR. E. PERRY McCULLAGH, Cleveland: The two questions refer virtually to the same thing. We have been interested in the problem for a long time, and in one of our previous publications we purported to show that large doses of testosterone propionate given to certain persons did apparently cause a more rapid epiphyseal closure than had appeared previously and in 1 or 2 there was a more rapid than normal closure of the epiphyses. We do not know whether that will occur with this material or not. So far there is no evidence that it does, but it is a factor that must be considered seriously, because it may work just as do the hormones which are secreted in certain adrenal tumors, in which rapid growth is connected with rapid epiphyseal closure. Under these conditions persons grow more rapidly than normal, but the rate of epiphyseal closure not only exceeds normal but exceeds the growth rate as well, so that the individual affected is eventually shorter than normal. We have seen rapid growth of this type in 1 person, who is already 6 feet (182 cm.) tall. In such cases care should be taken not to continue growth unless the epiphyses can be closed at a rate which is parallel to the growth rate.

Effect of Extracts of Anterior Lobe of Pituitary Gland on Diabetes, Retarded Growth and Sexual Development

DRs. JAMES A. GREENE, L. E. JANUARY and L. W. SWANSON, Iowa City: The effect of administration of extracts of the anterior lobe of the pituitary gland has been observed in 3 patients with diabetes mellitus and dwarfism. The alterations produced in the calcium, phosphorus, nitrogen and sulfur metabolism, the growth rate, the sexual development and the diabetes were ascertained. The metabolic studies showed an immediate and a later effect of the extract. The growth rates increased and sexual development occurred. The diabetes was improved in the patient 26 years of age but was not altered in the two 17 and 18 years of age.

DISCUSSION

DR. HENRY T. RICKETTS, Chicago: What extract was used and what was the dose? And was the extract tested in animals to determine whether it has a diabetogenic factor in large doses? I think it is interesting that the extracts which seemed to be effective in producing growth apparently did not affect the diabetes. I am not sure that the effect of the extract on growth has been clearly established. Children who have controlled diabetes may grow without anything else having been done. The first patient presented was sent home from the hospital and was supposed to be on good control while at home. However, he returned to the hospital with an increase in insulin requirement, having stopped taking pituitary extract and also stopped growing. Does this mean that the pituitary extract had been effectively used, or does it simply mean that the patient was a little lax in his diet at home and when admitted to the hospital was again controlled with large doses of insulin and, as would be expected, resumed growth?

DR. W. O. THOMPSON, Chicago: What pituitary extract was used? We have tried to produce growth in man with pituitary extracts and so far we have not been able to find one that definitely accomplishes this end.

DR. JAMES A. GREENE, Iowa City: The extracts used were those marketed by Parke, Davis & Co. What made our first patient's diabetes get better, I do not know. It is true that his diabetes got worse at home and was probably due to laxity

in the diet. We now have several patients with dwarfism who have grown; the oldest is a man aged 26 whom we have followed for four years. He has grown 3¼ inches (9.5 cm.), the epiphyses have closed, and he looks like a man now. One factor which has to be taken into consideration is that we have to give these extracts time to work.

Secretin in Determining Pancreatic Function

DR. H. M. POLLARD and LILA MILLER, PH.D., Ann Arbor, Mich.: By the use of secretin, pancreatic-duodenal juices have been secured and analyzed with respect to concentration of amylase, trypsin, bicarbonate, bile pigments and hydrogen ion concentration. Thirty-one persons were used as subjects to furnish data for the pancreatic response. They included a control group of 8 normal persons and in addition 5 patients with severe diabetes, 7 with carcinoma of the pancreas, 7 with pronounced cholecystic disease, 2 with stone of the common bile duct, and 2 with chronic pancreatitis. On the basis of these data, the value of this test as a diagnostic aid was considered.

DISCUSSION

DR. HENRY T. RICKETTS, Chicago: A patient recently studied had severe general calcification of the pancreas with complete pancreatic achylia yet with his diabetes controlled by as little as 10 units of insulin. Therefore a disturbance of the external pancreatic function does not necessarily imply great severity of the diabetes itself.

DR. CLARENCE BERNSTEIN, Chicago: If there is a carcinoma in the body of the pancreas the external secretion may be disturbed, but in the cases of carcinoma of the head of the pancreas presented the figures show that there was much bile in all specimens of duodenal contents. Were these cases of completely obstructive jaundice and did they show jaundice clinically?

DR. WALTMAN WALTERS, Rochester, Minn.: Most of the obstructions caused by cancer of the head of the pancreas are not true anatomic obstructions but are functional. One can demonstrate that the lumen of the pancreatic portion of the common bile duct has been squeezed but not completely occluded by the tumor in the head of the pancreas. This squeezing is occasionally due to inflammation associated with the carcinoma. At the present time, in the management of lesions of the biliary tract errors sometimes occur in determining the presence or absence of associated chronic pancreatitis. The surgeon is dependent on the feeling of the pancreas to determine whether chronic pancreatitis is present. Postoperatively there is an opportunity to check the diagnosis by cholangiographic studies. If pancreatitis persists, its squeezing effect on the pancreatic portion of the common bile duct is apparent not only by the narrowing of its lumen and a persisting increase in the mid-portion of the duct but by delay in the emptying time of the duct as well. Improved tests of pancreatic function have been of considerable assistance in determining the presence of pancreatic disease. This has been true not only as far as the study of external pancreatic secretion itself following the intravenous injection of secretin, as originated by Lagerlöf, is concerned but also in the study of values for the activity of amylase and lipase in the serum, as Comfort and Osterberg have shown. These observers have found the values for amylase and lipase to be almost constantly elevated if determined within a few days after the onset of acute pancreatitis. The values for amylase usually return to normal within three or four days, whereas those for lipase may be elevated for as long as ten to fourteen days or longer after onset of the attack. Comfort and Osterberg have shown also that increased concentration of lipase in the serum in cases of obstructive jaundice denotes that the pancreas is involved in the process; if the clinical data point to malignant obstruction, the elevation of values for serum lipase localizes the malignant condition in the pancreas rather than in the biliary tract, for these authors have shown that normal values for serum lipase obtain almost universally in malignant lesions of the biliary tract.

DR. H. M. POLLARD, Ann Arbor, Mich.: The test requires much more study and analysis, especially on normal persons, before we shall be able to evaluate abnormal readings. In doing these thirty-one tests throughout last year, we utilized a full time chemist for the analyses, and, in addition, Dr. Miller and I

devoted considerable time to the details of obtaining the samples and assisting in the analysis. Consequently at the present time I do not consider that the test is a simple one, but I am convinced that it offers valuable information. In answer to Dr. Bernstein, the patients who had carcinoma of the head of the pancreas with obstruction did show clinical jaundice. The cost of the material is still high, and I do not know of any other source than the one pharmaceutical house in Sweden. The suggestion of repeating the test after removal of the obstruction to the pancreatic duct is an excellent one. We have not done this but it would add positive information. The use of this test in evaluating the presence or absence of pancreatitis offers good theoretic possibilities, and we have been able to apply it in 2 cases with confirmatory results. I believe that the test has a definite value in evaluating associated pancreatic disease in the presence of severe disease of the gallbladder.

A Study of Gold Metabolism and the Fate of Gold Injected in the Treatment of Arthritis

DR. R. H. FREYBERG, W. D. BLOCK, PH.D., and O. H. BUCHANAN, M.S., Ann Arbor, Mich.: While patients with rheumatoid arthritis were receiving increasing amounts of either myochrysine, gold sodium thiosulfate or aurothioglucose at weekly intervals (for approximately six weeks), the concentration of gold in the blood and the urinary excretion of gold were measured daily by a new, highly sensitive, photoelectric colorimetric method. In addition, on the day of administration of the gold salt the content of gold in the blood and urine was determined one, two, four, six and twenty-four hours after injection. After the weekly dose of medicine became standardized similar determinations of gold were made at approximately monthly intervals throughout the period of treatment and for several months thereafter. Occasionally the concentrations of gold in synovial fluid and blood were measured simultaneously. In many other patients occasional determinations of gold in blood and urine were made during and after periods of chrysotherapy.

As the amount of gold salts administered was increased in the manner commonly employed, the blood concentration and urinary excretion of gold increased slightly but the elimination was much slower than the rate of administration, so that gold remained in the body in significant amounts often for months after its administration ceased.

DISCUSSION

DR. WALTER L. PALMER, Chicago: This last year we looked up the literature on gold therapy to see if there is any valid evidence that this new cure is better than any other new cure for arthritis. We were not able to convince ourselves that there is any real advantage in gold therapy over any other therapy, including psychotherapy. There is good evidence that gold therapy is dangerous and so, until we can prove that it has some value, it seems to me that the medical profession should not use it as generally as it is now being used. There came to our attention last spring a woman aged 47 who, because of mild arthritic symptoms, had been given by her physician four injections at weekly intervals of gold thiosulfate, 50 mg. a dose, receiving a total dose of 200 mg. She had no symptoms of toxicity until after the last injection. Six days after this last injection she suffered nausea and vomiting and diarrhea. These symptoms persisted for ten days. The patient was brought to the hospital in a stage of acute dehydration with profound diarrhea and died six days later. The autopsy showed extensive ulcerative gastroenteritis, particularly involving the ileum; the mucosa was entirely gone. Chemical studies disclosed the presence of gold in all tissues studied, particularly in the liver and spleen and intestine. The death occurred about three weeks after the last injection of gold, and all the symptoms occurred after the last injection.

DR. CARL V. MOORE, St. Louis: I was much interested in the appearance and increase of gold in plasma. Do the authors know in what form this gold is present? Is it hooked up, for instance, with the serum globulin?

DR. CLARENCE BERNSTEIN, Chicago: Could gold sulfide be recovered in the stool, and, if so, would this be a better indication that it had not been absorbed?

DR. CHARLES A. DOAN, Columbus, Ohio: What proportion of patients who tolerated this treatment seemed to be clinically improved? Has any type of allergic reaction been noted early in the course of gold therapy in those patients who did not tolerate it so well?

DR. CECIL STRIKER, Cincinnati: What is the time relationship between the injection of gold and the appearance of gold in the synovial fluid, and how long after injection is discontinued does the gold persist in the synovial fluid?

DR. R. H. FREYBERG, Ann Arbor, Mich.: Our paper is entitled "A Study of Gold Metabolism" and we did not plan to discuss the problem of clinical value. We prefaced this discussion with the statement that we had observed definite benefit which we thought was due to the use of gold salts, but we also observed reactions which were serious in some cases. We observed our patients carefully for a long time before gold therapy was used. We have seen many patients who, when given gold, had definite clinical benefit that persisted for as long as we have followed them, so we feel that gold therapy has value in some patients. I should like to know whether Dr. Palmer has observed many patients treated with gold when he questions its value. I questioned its value before I used it. In some patients there is no benefit. We do not recommend the use of gold salts by general practitioners as the treatment exists at present. Before we use gold salts we explain the situation and let the patient decide whether or not he wishes this form of treatment; we give an honest evaluation of the possibility of good and harm, and if he wants it used we employ it. We are extremely careful in its use and make frequent examinations of the blood and urine for any indication of intolerance. I am sure that if great caution is used intolerance will often be recognized and many serious reactions avoided. The length of time the drug is used, the dose and the route of administration are important with regard to reactions. We believe that intravenous administration is not the preferable route. We have not observed any benefit before six or eight weeks after treatment is begun; consequently we see no justification for the intravenous use of a drug which acts so slowly if it can be successfully administered by another route. On the basis of the results of our metabolic studies and because we have encountered more reactions with large doses of the drug, we are at present using doses smaller than are commonly employed. I am sure this is safer. In answer to Dr. Moore's question, we have not determined the form in which gold exists in the blood. We have separated the corpuscles from the plasma and then have found gold only in the plasma. We have to date used colloidal gold sulfide only by intramuscular and oral administration. Dr. Bernstein asked whether analyses have been done on feces. We are doing that now in our study of patients and have studied this in animals. We have found some gold in the feces of animals given gold salts intramuscularly, but whether after colloidal gold sulfide has been given orally there are significant amounts of gold in human feces needs to be determined. We have observed some patients soon after the drug has been given intravenously who show a relatively small amount of gold in the blood. Our studies on animals have shown that the reticuloendothelial cells of the liver and spleen take up gold when it is given as colloidal aurothioglucose, intramuscularly. We cannot answer Dr. Doan's question about the incidence of toxic reactions. We do not see a large number of patients. About 1 in 4 patients we treat with gold salts will not be able to tolerate the drug, but often we stop treatment on extremely slight evidence of intolerance. We estimate that about 75 per cent of the patients who have been able to tolerate the drug and who have continued treatment have been benefited by it.

Prevention of Peritonitis

DRS. J. A. BARGEN, W. J. TENNISON and C. F. DIXON, Rochester, Minn.: This is an analysis of the effect of antiperitonitis vaccine in 3,000 patients who had surgical procedures performed on the large intestine. A mixture of the green-producing streptococci and *Escherichia coli* have been used in a vaccine against peritonitis in patients who were to have intestinal operations since October 1928. The early impressions from the use of this vaccine as part of a preoperative program were favorable. In recent years a well controlled experiment has been

conducted in which every alternate patient who anticipated an intestinal operation received the vaccine.

DISCUSSION

DR. JOHN G. MATEER, Detroit: To what degree has the dose of the vaccine been reduced in order to avoid the more severe febrile reactions and the resulting higher mortality from subsequent peritonitis of patients having reactions of this type?

DR. GEORGE E. WAKERLIN, Chicago: Was there any preliminary experimental work on animals?

DR. J. A. BARGEN, Rochester, Minn.: Animal experiments were performed by Dr. Siegfried F. Herrmann at the Institute of Experimental Medicine under the direction of Dr. Mann. Extensive experiments were performed in which dogs were inoculated with fecal streptococci and *Esch. coli* intraperitoneally. After the injection of such a bacterin extensive intestinal operations were performed on the dogs. The incidence of fatal peritonitis in dogs so treated was low, whereas the incidence of peritonitis in a similar series of dogs which did not have the vaccine preoperatively was high. It was these striking results which led us to administer a similar vaccine to human beings before performing major intestinal operations. Reduction in fatal peritonitis in patients who have had such a bacterin has been striking. The problem has been studied from many different angles. There is a reduction in the total number of patients who have succumbed to peritonitis, there is a greatly reduced incidence of peritonitis when one considers the problem by operation, and there is a decided reduction in mortality when one considers the problem by surgeons who have operated. In reply to Dr. Mateer's question about the dose, I would say that a total of 1 cc. of a mixture consisting of equal parts of streptococci and *Esch. coli* suspended in 10 cc. of physiologic solution of sodium chloride is given intraperitoneally. Such a mixture will contain about 500 million of the killed streptococci and 500 million colon bacilli.

Circulating Blood Volume in Human Subjects Exposed to Hot Environments

DR. FORD K. HICK, NATHANIEL GLICKMAN, M.S., and DRs. M. M. MONTGOMERY and ROBERT W. KEETON, Chicago: Healthy medical students were the subjects of experiments. Under basal conditions an initial determination of the blood volume was carried out by the dye injection procedure (T1824) while the conditions were comfortable for the nude subject. On its completion the temperature was increased so that regulation of evaporative heat was dominant and after an appropriate length of exposure (one hundred to two hundred and fifty minutes) the determination of the blood volume was repeated.

After fairly short (one hundred minutes) exposure to a temperature of about 98 F. an increase in the volume of circulating blood has been observed amounting to 11 per cent, despite considerable loss of water from the body by evaporation. In a longer exposure to extremely hot conditions (112 F. for two hundred and twenty minutes), a fall of as much as 7 per cent in blood volume has been observed. After free sweating in hot conditions certain subjects showed no change in blood volume even after losing as much as 900 Gm. of water in sweating.

Changes in blood protein reflect the concentration and dilution of plasma implied. Leukocytes or red cell counts do not accurately indicate these adjustments.

Certain subjects, presumably more facile in their regulation of heat, can withdraw water for sweating from stores within the body without affecting the circulating body fluids.

DISCUSSION

DR. ROBERT W. KEETON, Chicago: Estimations of the plasma volumes from day to day do not always show the same values. The exposure of the body to warm environments causes a peripheral vascular dilatation and a transfer of blood from the interior of the body to the exterior. This is mirrored by the reduction of the blood in the lungs, as shown by the increase in the vital capacity. When a subject stands on his feet there is a decrease in the circulatory volume of blood, which returns to its original value after thirty to sixty minutes. All these facts indicate that there is a rather ready exchange between the volume of active circulating blood and the volume of reserve blood. The requisitioning of new supplies of blood from this source is one of the

first adjustments of the circulation to increased temperatures. This in turn leads to the conclusion that the blood volume is undergoing all the time phasic adjustments, and its value at any one time is dependent on the physiologic state of the person at the moment.

DR. GEORGE E. WAKERLIN, Chicago: Has Dr. Hick determined with what rapidity these changes occur in the normal human being?

DR. FORD K. HICK, Chicago: These changes take place in the human being rather rapidly within forty minutes or sooner. With regard to animal experiments on heat regulation, I do not believe there is any possibility of transmitting any data from animal to human physiology in such an experiment because of the difference in heat-regulating mechanisms.

The Clinical Value of Sleeping in the "Head Up" Position

DRs. A. R. MACLEAN and E. V. ALLEN, Rochester, Minn.: Man is one of the few animals which lead a life in two planes, the vertical during activity and the horizontal during sleep. As a result of this postural change, he is susceptible to ailments which have postural components. We have studied two such disorders, orthostatic hypotension and orthostatic tachycardia. Our studies indicate that therapeutic methods which diminish the range of postural change have a place in the treatment of these disorders.

In primary orthostatic hypotension, as well as in secondary orthostatic hypotension after extensive sympathectomy for essential hypertension, the use of the "head up" bed has resulted in great improvement in the arterial blood pressure in the erect posture. The symptoms of syncope and weakness in the erect posture have dramatically disappeared, and patients are capable of existing in the upright position during the day. However, sleep in a horizontal bed perpetuates the inability to stand erect or completely destroys the advantages gained by sleeping in the head up position.

Some patients with orthostatic tachycardia, a syndrome which in many instances is comparable to those designated as "effort syndrome," "irritable heart" or "neurocirculatory asthenia," have been relieved of their symptoms by sleeping in the head up position. Likewise some patients with hypertensive headaches which occur only at night have been benefited. Other conditions have been studied. The physiologic adjustments which follow this type of treatment are complex, but some of them are fairly well understood.

DISCUSSION

DR. JOHN W. SCOTT, Lexington, Ky.: Certain it is that since the days of early English physiologists we have always thought that man compensated for the upright position by splanchnic control, and yet, as I understand the paper, the authors assume that this has little or nothing to do with the relief of these patients but rather they ascribe it to a better return of venous blood. It seems to me difficult to understand why perhaps we all should not sleep upright. Would we be better off? We pay the price for the assumption of the upright position and I find great difficulty in explaining these interesting results the way the authors have done.

DR. E. V. ALLEN, Rochester, Minn.: This simple procedure will not benefit simple morning exhaustion without a postural component defined as orthostatic decrease in blood pressure. Moreover, in our experience it has not benefited 3 patients who have had epilepsy which occurred chiefly at night. It has benefited several patients who have headache on awakening or who are awakened by headache. It is important to remember that since patients who complain of morning exhaustion improve during the day subjectively and objectively the study of blood pressure and pulse rate must be carried out in the morning, for objective evidence which accounts for symptoms may be absent or minimal in the afternoon.

DR. J. DEWEY BISGARD, Omaha: Often normal surgical patients, when first getting out of bed after an operation, complain of dizziness and may collapse with a big fall in blood pressure as do patients with postural hypotension. Those patients kept in Fowler's position after operation have fewer of these symptoms than do those kept flat in bed.

Dr. A. R. McLEAN, Rochester, Minn.: Our conception of orthostatic hypotension has changed significantly. We previously thought that the hypotension represented a disturbance of the sympathetic nervous system. We now feel that the drop in blood pressure is merely a secondary phenomenon resulting from diminished return of venous blood. This defect in return of venous blood can be demonstrated by the Flack test. The evidence of a disturbance in the autonomic nervous system had been the lack of a cardiac accelerating mechanism, a deficiency in sweating and the drop in blood pressure on standing. In our cases of orthostatic hypotension we have been able to demonstrate normal arteriolar reflex vasoconstriction and vasodilatation as a result of changes in environmental temperature. In 1 case, in which remarkable improvement occurred from the use of a head up bed, we have been able to demonstrate the reestablishment of normal sweating. It appears to us that in cases of orthostatic tachycardia orthostatic hypotension would develop if the cardiac accelerating mechanism failed.

Rate of Diodrast Excretion During Intravenous Urography as a Test of Renal Function

DRS. JOSEPH C. EDWARDS, THOMAS FINDLEY and H. L. WHITE, St. Louis: The large amount of diodrast required intravenously for roentgen visualization of the renal pelvis imposes a far heavier load on the function of tubules than do the amounts of phenol red and other dyes in common use. The iodine method of White and Rolf has been made suitable for routine office use, and the amount of diodrast excreted during the thirty minutes following injection has been compared with simultaneous urea clearance. Normal adults excrete about 40 per cent of the injected iodine under the conditions usually employed in pyelography. The effects of dehydration, fasting and pitressin have been examined, and normal value has been established in adults for the usual quantities of both diodrast and diodrast compound. The test measures neither the flow of renal plasma nor the T_m (maximal tubular excretion) value of Smith but appears to be a valuable addition to urologic technic because it is fully as sensitive as urea clearance, requires no complicated analytic procedure and imposes no additional expense or inconvenience to the patient undergoing roentgen study.

A group of twenty-eight City Hospital interns and Washington University Medical School students were studied as a normal group. All had normal urea clearances, blood pressures, blood urea nitrogen levels and urine.

A group of 12 patients with various degrees of essential hypertension, chronic glomerular nephritis and cardiac decompensation were studied. Urea clearances were performed simultaneously in 2 normal and 3 abnormal patients. Diodrast inulin clearances were also done and were well correlated with the diodrast iodine excretions in the thirty minute period. The blood iodine is at maximal tubular excretion for the first fifteen or twenty minutes of the test.

The abnormal group excreted about 30 per cent of 2.3 Gm. of iodine injected as 20 cc. of diodrast in thirty minutes, while the normal was 40 per cent. The worse the renal function, the less iodine there was excreted. There was comparatively little difference among tests done before breakfast (during fasting) and those done after the subjects had food.

The effect of pitressin decreased the urea clearance without appreciably affecting the excretion of diodrast.

Excretion of Porphyrin in the Urine in Alcoholic Cirrhosis and After Episodes of Hepatic Coma

DR. SAMUEL NESBITT, Rochester, Minn.: During a qualitative and quantitative study of the excretion of ether-soluble porphyrin in the urine of patients suffering from a variety of hepatic diseases, 4 instances of severe alcoholic cirrhosis of the liver were encountered. The persons concerned were observed for extended periods during which they exhibited repeated transient episodes of neurologic manifestations ranging from confusion and mild psychotic states, sometimes with pathologic neurologic signs, to deep hepatic coma. By means of daily quantitative determinations it was ascertained that these patients excreted abnormally large amounts of coproporphyrin in their urine and that this value was diminished before and during

periods of acute hepatic insufficiency, only to be abruptly increased as the patient emerged from the acute episode. The porphyrin has been isolated and identified as coproporphyrin I and III.

DISCUSSION

DR. C. J. WATSON, Minneapolis: I agree that the variation in the excretion of porphyrin in these cases represents a variation in clearance. These patients have profound hepatic damage with suppression of renal function. We have seen a similar example in a patient with acute porphyria excreting large amounts of the zinc complex of uroporphyrin. This patient was admitted to the hospital with severe abdominal colic, severe vomiting and moderate dehydration. During the first twenty-four hours the urinary output was 160 cc.; this increased rapidly, probably as a result of the parenteral administration of fluids and dextrose. With this there was an increase in the output of the zinc complex from 10 mg. during the initial phase to 90 mg. when the fluids had increased. In the past it has been customary to determine simply the total excretion of coproporphyrin in the urine. Our information so far has concerned only the values for the total of the two isomers. In the future increased importance will undoubtedly become attached to the ratio between isomer types I and III in the urine and feces since it is certain that coproporphyrin I has significance entirely different from that of the type III isomer. The synthesis of the type I isomer is independent of hemoglobin synthesis, although the available evidence indicates that the formation of type I is related in some way to the rate of erythropoiesis in the bone marrow. Therefore it is not surprising that patients with cirrhosis who have a red bone marrow and not infrequently have at least a mild increase in the rate of destruction of the blood should exhibit increased formation and excretion of the type I isomer. Also, because of the hepatic damage, there is a shunt of the coproporphyrin I into the urine so that with cirrhosis of the liver we commonly encounter increased type I in the urine. This is comparable to urobilinogen excretion in similar cases. Patients with macrocytic anemia with excessive amounts of urobilinogen in the feces and large amounts in the urine have an oversupply of the substance with inability of the liver to handle the amounts returned to it. The question of significance of the type III isomer is more difficult of interpretation. On theoretic grounds the formation of this isomer could be regarded as related to the formation or destruction of hemoglobin. There is no evidence that coproporphyrin III is formed during the simple destruction of hemoglobin, but there is much evidence that it is formed when there is a disturbance of the formation of hemoglobin in the bone marrow, as in lead poisoning or other types of poisoning. It is of interest that some patients with cirrhosis have been noted to have a predominance of type III in the urine. Most patients, it is true, excrete chiefly the type I isomer. The fact that excretion of type III has been noted in some and that this is most often associated with some form of poisoning may provide a means in the future of obtaining more information about the etiology of hepatic cirrhosis.

DR. HUGH R. BUTT, Rochester, Minn.: Were vitamin supplements given and, if so, was there any apparent effect on the excretion of porphyrin?

DR. SAMUEL NESBITT, Rochester, Minn.: It is interesting that these patients did recover from such acute episodes, and this may be attributed to the intensive vitamin therapy, since that was the one innovation in their medical care. The routine management always included vitamin supplements, and at the first appearance of what might suggest the onset of such an acute episode of hepatic insufficiency intensive vitamin therapy was instituted which included the daily intravenous administration of at least 100 mg. of nicotinic acid, 100 mg. of thiamine hydrochloride, 100 mg. of ascorbic acid and 1 to 2 mg. of a vitamin K preparation. We were never able to demonstrate to our satisfaction that any one of these vitamins or any combination of them produced any decrease in the excretion of porphyrin in the urine of many patients having various diseases of the liver. When the particular patients were receiving the most intensive vitamin therapy and after they had responded to treatment, the excretion of porphyrin in the urine was abruptly increased.

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Hemoptysis in Rheumatic Heart Disease.—Wolff and Levine state that among the 521 patients with rheumatic heart disease admitted to the Beth Israel Hospital between 1928 and 1937 inclusive 50 had hemoptysis prior to admission or during hospitalization. The symptoms associated with the hemoptysis varied; some patients had none, others complained of pain in the chest, palpitation, dyspnea, cyanosis, wheezing, acute pulmonary edema, weakness, faintness and collapse. The three most common symptoms were palpitation, pain in the chest and dyspnea. The average age of the patients was 33.4 years; the youngest patient was 14 and the oldest was 54. Mitral stenosis was present in every case (except one, in which the hemorrhage was caused by a lung abscess), pulmonary infarction was diagnosed in 23 and, prior to the onset of hemoptysis, congestive failure was present in only 8 cases. The hemorrhage was accounted for by pulmonary infarction in almost half of the patients. Pulmonary infarction was found in 7 of the 8 cases of congestive failure and in only 2 of the 9 cases in which the size of the heart was normal. Following the initial hemoptysis the size of the heart increased progressively over a period of many months and, at postmortem examination of one of them, pulmonary arteriosclerosis and multiple thrombosis were found. Pulmonary infarction is the most likely cause of hemoptysis in the presence of congestive failure, but if the patient has no cardiac enlargement it can be excluded. If pulmonary infarction is present in the absence of cardiac enlargement, and particularly if hemoptysis is followed by a progressive increase in the size of the heart, pulmonary arteriosclerosis may be the underlying cause. In most of the remaining cases the hemoptysis was caused by mitral stenosis alone, without gross evidence of congestive failure. Hemorrhage may be caused by active

rheumatic infection. There was such evidence in 12 cases. When hemoptysis occurs in a case of rheumatic heart disease and intercurrent pulmonary disease and left ventricular failure can be excluded, it may be assumed that mitral stenosis is present. Hemoptysis in such cases may help to distinguish between an Austin-Flint and an aortic regurgitation murmur, or in the diagnosis of mitral stenosis. At the time at which this study was completed, the authors point out that 33, or 66 per cent, of the 50 patients are dead; the average survival following the initial hemoptysis was thirty-two and a half months, varying from one day to more than five years. The average interval from the initial hemoptysis to the last follow-up examination of the 17 patients who are still living has been thirty-nine months and, to date, only 5 of these have survived five years or longer. Half of the patients with slight cardiac enlargement died within one or two days after hemoptysis, and two thirds died within a year. As these deaths were of patients in whom the prognosis was usually excellent, it is obvious that hemoptysis in such cases is a grave prognostic indication. Among the remaining patients the mortality was higher and the survival shorter than would have been expected of patients with cardiac enlargement and congestive failure alone. The mortality was higher among the patients with pulmonary infarction than in the series as a whole. Hemoptysis during pregnancy is not necessarily indicative of a bad prognosis, for the 2 pregnant women in the series survived the longest.

Healing of Tuberculous Nephrectomy Sinuses.—Greenberger and Helfert have used ozonized olive oil in the treatment of nonhealing incisions and sinuses following excision of a tuberculous kidney. They found that the oil stimulated healing and at the same time added to rather than detracted from the comfort of the patient. The technic consists of the daily instillation of a sufficient quantity of the ozonized olive oil to fill the sinuses completely. Since this preparation contains heat, moisture, labile ozonides of triolein and other unsaturated hydrocarbons, significant quantities of nascent oxygen are released into the tissues of the sinus walls, where it acts as a bactericidal agent and a stimulant to local cellular metabolism. Thus sterilization of the wound and proliferation of tissue are promoted without destroying surrounding healthy tissue. Under this therapy the wounds have in most cases healed at a constant and satisfactory rate. The exposed surfaces of gaping lesions assumed a clean and fresh aspect without excessive granulation or sloughing. Of the 15 cases in which solution of triolein ozonide in olive oil was used the sinuses in 13 have healed completely in from two to five months. One wound which showed no evidence of healing during two months with other types of therapy healed readily under this treatment to such an extent that revision was easily done. In the fifteenth patient the wound was healing satisfactorily and only a single small sinus remained when the patient left the hospital without consent.

Cardiac Lesions Associated with Chronic Infectious Arthritis.—At necropsy in 25 cases of chronic infectious (rheumatoid) arthritis Baggenstoss and Rosenberg demonstrated cardiac lesions in 20. Lesions identical with those of rheumatic fever were observed in 14 (56 per cent). Nonrheumatic cardiac lesions were present in 6 (24 per cent). In 10 of the 14 cases in which there were rheumatic lesions there was microscopic evidence that the inflammatory process was still active and progressive when death occurred. In 7 of these 14 instances the heart disease was judged to be an important factor in causing death. Also in only 7 of these 14 patients had signs or symptoms of heart disease been present during life. The high incidence of rheumatic cardiac lesions suggests a relationship between chronic infectious (rheumatoid) arthritis and rheumatic fever.

Old Age Pneumonia and Effect of Pneumococcus Polysaccharide.—Kaufman reports the work done with active immunization against pneumonia of inmates (more than 50 years of age) of the New York City Home with a capsular antigenic polysaccharide containing specific substance for type I and II pneumonia. During the winter of 1937-1938, 1,000 persons were immunized with 0.5 cc. of the polysaccharide containing 1 mg. of each active substance, and 1,120 persons were kept as controls. In 1938-1939 the same method was used except that 500 new patients were divided in such a way that every other one was inoculated with 0.5 cc. and alternates were kept as controls. Another thousand were taken from the old inmates and 500 were inoculated with 1 cc. containing 2 mg. of each active substance and 500 who had served as controls the previous year were again used as controls. In the first year there were 14 cases of pneumonia with 8 deaths among the 1,000 immunized persons. Among the 1,120 nonimmunized there were 63 cases of pneumonia with 47 deaths. The second year there were 9 cases of pneumonia with 5 deaths among the 750 immunized persons and 41 with 20 deaths among the 750 nonimmunized. When the second year's study is subdivided it is found that there were 4 cases of pneumonia with 2 deaths among the 250 inmates receiving 0.5 cc. of polysaccharide with 1 mg. of each active substance and 5 cases with 3 deaths among the 500 given 1 cc. containing 2 mg. of each active substance. In the smaller control group there were 15 cases of pneumonia with 8 deaths and in the larger control group 26 cases with 12 deaths. Among the total 1,750 inoculated persons there were 23 cases of pneumonia with 13 deaths, making the morbidity rate 13.13 and the mortality rate 7.4 per thousand. Among the total 1,870 controls the figures are 104 cases with 67 deaths and the respective per thousand figures 55.66 and 35.8. The course of pneumonia in the immunized group (length of disease

and frequency of complications) was apparently not influenced by the inoculations. The prophylactic value seemed more pronounced in the first three quarters than in the last quarter of the year after immunization. The data show that the incidence and mortality rates of pneumonia were reduced not only for the types from which the active substances were isolated but also for other types. Further observation is necessary to corroborate the data. A group like the one used is particularly suited for immunizations against pneumonia, as among such a population the high incidence, mortality and case fatality rates and the frequency of repeated attacks make active immunization a practical problem. As postoperative pneumonia is a dreaded complication in this age group, immunization with polysaccharide may considerably reduce its incidence.

Hemochromatosis.—Cantarow and Bucher report a case of hemochromatosis because of the following atypical factors: 1. Glycosuria was absent and the dextrose tolerance was significantly decreased in spite of the unusual quantity of iron in the liver and pancreas. 2. Iron-containing pigment in the apparently characteristically pigmented skin was absent. 3. Cutaneous xanthomatosis with hypercholesterolemia was present but diabetes was absent. 4. Deficiency in adrenal cortical and androgenic hormones was demonstrated at postmortem study. 5. The unusual cause of death, acute pancreatic necrosis, was apparently unrelated to the hemochromatosis.

Prostigmine Methylsulfate for Deafness and Tinnitus Aurium.—Ersner and his colleagues treated 59 cases of deafness and tinnitus aurium with prostigmine methylsulfate. Their results are contrary to those of their predecessors. The authors tested hearing with the audiometer and tuning forks. Tests were repeated twice a week. Four patients asserted that they had improved, but their audiometric readings disclosed no change. These patients said improvement continued even after administration of the drug was discontinued and physiologic solution of sodium chloride was substituted. Eighteen patients said that symptomatic improvement occurred soon after the first few injections, but here also improvement could not be verified by audiometer and tuning fork tests. After several weeks of treatment the euphoria and enthusiasm of the patients subsided, and the symptoms remained the same despite treatment. Eight patients after having received fifteen injections showed an 8 to 10 decibel improvement at varying times, but repeated hearing tests revealed that the improvement was neither permanent nor prolonged. Attacks of acute angina pectoris caused prostigmine therapy to be discontinued in 3 patients. The remaining 26 patients neither claimed nor showed any so-called improvement in the tinnitus aurium or hearing either during or after therapy.

Influence of Antepartum Vitamin K on Retinal Hemorrhage of the Newborn.—Maumenee and his associates point out that, although a few cases of true hemorrhagic diathesis with definite deficiency in the prothrombin have been reported, there has been no direct correlation between the prothrombin level of the blood and the incidence of neonatal hemorrhage. Since September 1939 the authors have given alternate mothers entering for delivery with a viable baby 2 mg. of menadione or a unit-equivalent vitamin K active substance. Fifty mothers in the treated series received an additional 2 mg. of menadione by mouth daily for at least four days before delivery. For six months the eyegrounds of all infants, with the exception of very premature ones, were studied for retinal hemorrhage. A total of 446 babies was examined; 173 were born to mothers who had received vitamin K during labor, 50 to mothers who had received prolonged vitamin K therapy and the remaining 223 to women who were not treated with vitamin K. In 26 infants with retinal hemorrhage, born of untreated mothers, the average plasma prothrombin level was 16.7 dilution units as against the average infant plasma prothrombin level of 28 dilution units. Babies with retinal hemorrhage then tend to show a diminished prothrombin level, but no direct correlation between the extent of the retinal hemorrhage and the degree of the hypoprothrombinemia could be demonstrated. The plasma prothrombin level of infants born to mothers receiving vitamin K was usually elevated. However, 21 such infants who had retinal hemorrhage showed an average prothrombin of 31 dilution units. Failure to promote a rise would seem to indicate either an extremely low prothrombin value before therapy, a resistance to intrapartum therapy or retinal hemorrhage early in labor; that is, before antepartum treatment. The latter is supported by hemorrhage in babies born by cesarean section performed during the early stages of labor. As the prothrombin levels of infants with hemorrhage born of untreated mothers are lower than in normal infants a reasonable explanation of retinal hemorrhage in this treated group would be one or a combination of the three foregoing factors. As intrapartum vitamin K may not provide complete prophylaxis against hypoprothrombinemia, 14 infants without retinal hemorrhage, whose mothers received vitamin K during labor, were picked at random for a control series. The average prothrombin levels of these infants were 44.6 dilution units. Only 2 of the infants of the 50 mothers who at term were given 2 mg. of menadione for at least four days and then labor was induced by artificial rupture of the membranes were found to have hemorrhages. Their prothrombin levels were 36.5 and 4.4 dilution units, respectively. The most probable explanation for this failure was a refractoriness of either the mother or the infant to vitamin K. The average level of 29 of the infants whose mothers were treated for at least four days was 56.1 units. Prothrombin studies done on mother and infant show that failure to respond to treatment with a vitamin K preparation was due to deficient absorption. Normal gallbladder studies indicated that this failure was not due to any abnormality of the biliary tract. Future studies may show whether or not this will be the explanation for all refractory cases.

Lowering of Blood Uric Acid by Uricase Injections.—Oppenheimer records the fact that a solution containing uricase if injected intravenously or intramuscularly into hens with a "gouty" or high plasma uric acid concentration will lower the uric acid level. The higher the plasma uric acid level, the greater the uricolytic activity of the enzyme. One determination of the duration of the uricolytic activity of a single uricase injection indicates that it lasts at least twenty-four hours. Two hens receiving weekly uricase injections for four and five weeks,

respectively, showed a decidedly lower average uric acid level than control hens on the same meat diet. Determinations over longer periods are needed to establish the validity of the observation. The work has not been in progress long enough to determine whether the relatively small dosage of uricase employed will prevent the appearance of tophi.

Bacteriophage for Furunculosis.—Dalitsch states that furunculosis in students of the professional schools of the University of Illinois has been most prevalent in the spring. He believes that the treatment of furunculosis is incomplete without a wider use of bacteriophage. Friction of clothing along the collar line, sleeves and buttocks seems to favor inoculation of the skin. Trauma (picking the nose, plucking hair and squeezing of comedones) may initiate the lesion. Well nourished and obese persons are slightly more prone to this affliction. When the furuncle was in an early stage and the inflammation still diffuse with no opening into the lesion, hot water fomentations were applied continuously until pointing had occurred. The fomentations were covered with parchment

paper and held in place with adhesive tape. They were changed about every hour or two. When the lesion had sufficiently localized, the center of it was usually covered with a thin skin, and the lesion was opened by merely lifting off the desquamated tissue. A small wick drain, consisting of a few threads of plain gauze, was carefully passed into the sinus leading into the lesion and continuous wet dressings saturated with bacteriophage were applied. The bacteriophage dressing was covered with parchment paper and held in place with adhesive tape, with its upper margin left open. Bacteriophage was dropped on the dressing through the open upper edge in sufficient amount and often enough to keep it moist. In the case of intranasal infections a loose cotton dressing soaked with the bacteriophage was inserted into the nasal passage so as to be in contact with the infected area. At intervals additional bacteriophage was added with a medicine dropper to keep the dressing saturated. The technic is based on direct contact of the bacteriophage with the infected tissues. Plain gauze and cotton dressings were used because antiseptics hinder the action of bacteriophage. The students missed no time from classes. In a series of more than 200 cases encountered over five years the results were uniformly gratifying. Pain was relieved soon after the bacteriophage was applied. In from six to twelve hours the site of the lesion appeared much smaller, and tension and tenderness were greatly diminished. Thick purulent exudate was changed into a clearer serous drainage. Healthy granulations were soon evident. Movement of the affected part was possible, and dressings were changed without pain. The course of the infection was shortened and convalescence rapid. The method is particularly applicable to intranasal and facial infection. Every practitioner is familiar with examples of fatal complications resulting from these lesions. Intranasal furuncles present a type of infection that is always looked on with trepidation and helplessness because little active treatment can be used and because manipulation and instrumentation are contraindicated. The bacteriophage method gives a more effective active therapy from which prompt improvement can be expected with a high degree of confidence. "Crops" of satellite boils do not recur.

Treatment of Neonatal Hypoprothrombinemia.—Lawson reviews the literature on the treatment of hypoprothrombinemia (hemorrhagic disease) of the newborn infant. He describes a microprothrombin test which makes repeated tests on infants safe and simple. The test is performed at the infant's bedside in a room with a temperature of not more than 80 F., by placing 20 cu. mm. of thromboplastin suspension in the well of a common, hollow-ground slide, using a 20 cu. mm. Sahli hemoglobin pipet. The infant's heel is washed with alcohol, dried and punctured with a sharp lancet so that the blood flows freely. Twenty cu. mm. of blood is drawn into a clean pipet, added to the thromboplastin and mixed with it for from five to ten seconds with a fine glass stirring rod. By tilting the

slide, the mixture flows back and forth until a sharp end point occurs when it clots. The time is measured with a stop watch from the addition of the blood to the time of clotting and is expressed as the "microprothrombin time." The test can be performed repeatedly without danger to the infant. The author's studies show that the antepartum administration of menadione is effective in preventing hypoprothrombinemia of the newborn infant. It may prove desirable to give this drug or a similar naphthoquinone daily to mothers during the last month of pregnancy. If this has not been done, oral administration after labor has begun is effective if as much as 4 mg. is given at least five hours before delivery. Unless a decided degree of hypoprothrombinemia exists at birth, the intramuscular injection of 1 mg. of menadione in sesame oil during the first twelve hours of life will prevent any subsequent hypoprothrombinemia. Bile salts are not necessary for absorption in the newborn infant without biliary obstruction. Intramuscular blood transfusion is not effective prophylactically or therapeutically. The author considers a microprothrombin time of 75 seconds or longer as indicating a serious prothrombin deficiency.

Histoplasmosis.—Rhodes and his associates cite the occurrence of histoplasmosis in an infant of 3 months, evidently the youngest on record of the 5 cases reported. A culture of *Histoplasma capsulatum* was obtained from the infant's blood stream twenty-four hours before death. The incidence of the disease has risen sharply in the past two years. It should no longer be considered a rarity and must be ruled out whenever a leukopenia, prolonged fever, splenohepatomegaly, anemia of doubtful etiology or chronic infection of the respiratory tract is present. The symptomatology can vary, but a diagnosis may still be made by finding the small, oval, encapsulated organisms (from 1 to 3 microns) in the mononuclear cells in peripheral blood smears, sternal bone marrow smears, discharge from otitis media, sections of spleen removed at splenectomy and biopsy sections of skin and lymph nodes. The fungus, which is characterized by large warty, thick walled chlamydospores attached to the fungus filaments, is moldlike. No specific therapy has had sufficient trial because diagnoses, except for 3 cases, have not been made until necropsy. Further trial of antimony preparations—antimony and potassium tartrate and trivalent and pentavalent organic preparations of antimony—is advised.

Hemoglobin Regeneration in Vitamin C Deficiency.—Lozner reports observations concerning hemoglobin regeneration in 5 patients with presumptive vitamin C deficiency (shown by complete chemical absence of reduced ascorbic acid from the

blood plasma) and moderate or mild anemia. The patients were treated with bed rest and a diet limited to whites of eggs, white bread, white soda crackers, butter, spaghetti, rice, bacon, corn syrup, tea, coffee and milk boiled for five minutes. Three of the patients presented the clinical picture of scurvy, 1 of pellagra and 1 of idiopathic hypochromic anemia. Four of the 5 patients showed satisfactory hemoglobin regeneration without vitamin C administration, even though on a diet containing only traces of vitamin C and vitamin B complex. In 3 of these 4 patients, the administration of ascorbic acid, after the initial hemoglobin regeneration, neither caused reticulocytosis nor increased the speed of hemoglobin increase. The remaining patient had clinical scurvy with melena and anemia. During the control period neither the melena nor the anemia disappeared. Coincident with vitamin C therapy the melena ceased, and reticulocytosis and hemoglobin regeneration ensued. Complete regeneration of hemoglobin of 2 patients did not occur until they were placed on yeast and a general diet.

Sulfanilamide for Acute Pelvic Inflammation.—Williams used sulfanilamide for the treatment of 72 patients who had acute pelvic inflammation. He compares the results with those obtained in 100 similar patients treated during the pre-sulfanilamide era by route bed rest, fluids, catharsis, ice or heat to the abdomen and hot vaginal douches. The patients given sulfanilamide received in all other ways the same treatment as the control series. There were no fatalities in either series. In the control series the temperature of 72 per cent of the patients fell to normal within one week after admission. Improvement of pain, tenderness and leukocytosis almost paralleled the fall in temperature. The average duration of the febrile reaction in the control series was six and seven-tenths days. The longest elevation of temperature elevation was thirty-five days. In 63 patients suffering from their first attack the average was seven and nine-tenths days; in 37 patients with recurrent attacks it was four and eight-tenths days. Seventy-two per cent of the sulfanilamide-treated patients also showed a normal temperature within one week. The average time for a normal temperature to appear was five and eight-tenths days. In primary attacks (44 patients) the temperature elevation averaged six days, whereas in recurrent attacks (28 patients) the average was five and seven-tenths days. The longest elevation of temperature was thirty-six days. This patient ultimately recovered after a pelvic abscess developed and broke through into the rectum just as she was being prepared for colpotomy. A pelvic abscess formed in another patient while she was under sulfanilamide treatment. It was drained by colpotomy on the seventh day after admission; the temperature fell to normal two days later. These 2 cases are regarded as absolute failures of sulfanilamide therapy. Of the control patients 13 per cent and of those treated with sulfanilamide 11 per cent were deemed to require salpingectomy. The dramatic results often obtained with sulfanilamide in streptococcal infections and with sulfanilamide and sulfapyridine in pneumonias were disappointingly absent.

Diabetes Mellitus and Pregnancy.—Notlmann states that 5 diabetic women with a past history of several abortions and stillbirths were successfully delivered by prophylactic cesarean section. The influence that pregnancy will have on the diabetes of the mother cannot be predicted in spite of careful treatment. Repeated pregnancies in the same patient may take different courses. The author describes a state of hypoglycemia in infants of diabetic mothers during the first days of life which is sometimes accompanied by periods of unconsciousness. Its cause is the hypertrophy and overfunctioning of the pancreas. The cholesterol level of the 5 newborn babies ranged from 58 to 74 mg. per hundred cubic centimeters. Only 1 baby had a value of 162 mg. An icterus neonatorum later developed in this infant. The children developed well and continued to be healthy. Considering the extremely high mortality rate that exists among the fetuses and children of diabetic women, prophylactic cesarean section is recommended to save the life of the fetus, whose life is in greater danger than the mother's.

Periodontia in Internal Medicine.—Miller and Arvins believe that the danger of internal infection from periodontal foci (pus pockets, gingivitis and the like) is much more potent than that from periapical disease. They list the following reasons: 1. A much greater zone is involved than in a periapical abscess, considering the total surface area of the walls of all pockets. At least twenty times the absorption surface is involved in an average case of periodontal disease as in a well developed chronic periapical abscess. 2. Absorption from the gingival crevice is more rapid, as the blood and lymph supply to the gingiva is much greater than to a periapical area in bone, especially when the latter is surrounded by even a slight degree of condensation. Round, Kirkpatrick and Hails have shown that the force of mastication is sufficient to pump bacteria and their toxins into the circulation. 3. Resistance to bacterial growth is lower in the gingival crevice than anywhere else in the oral cavity because of stagnation and food accumulation. The depths of gingival crevices and periodontal pockets offer an ideal incubation zone for strains of streptococci which grow best in a low oxygen environment. Therefore the authors point out that not only should any comprehensive search for foci of infection include roentgen evidence of lesions at the apexes of teeth but the study should encompass the alveolar margin for activity of bone destruction and a thorough clinical examination for gingival disturbances which have not as yet affected the bony structure. The amount of bone loss is not as significant as the type of bone which remains, for this determines the activity of periodontal disease. Periodontal disease is primarily dysfunctional in origin, and the disturbing factors producing a "locus minoris resistentiae" may be broadly grouped as functional, traumatic and systemic (endocrine, allergic and nervous). The primary therapeutic procedure is the restoration of functional coordination of the teeth so that stress is evenly divided and there is no strain in any excursive movements. In young persons orthodontia may be beneficial, in adults it should always be followed by the shaping of the teeth to conform to the patient's age and functional requirements. Dietary deficiencies or systemic diseases which may be causing or complicating the local disease must be attended to. The direct local requirement of a fibrous, detergent diet is of equal importance to the mineral, vitamin and other dietary requirements for oral health. Pus pockets must be eliminated by surgical gingivectomy, conservative surgery or conservative subgingival curettage. The etiologic factors of periodontal disease are rarely, if ever, single. Periodontal disease can be cured, and the resulting improved health can be maintained.

Irradiation for Plantar Warts.—The Montgomerys report the results of treating 583 patients with plantar warts exclusively by means of roentgen rays. Of the 487 patients whose end results are known, 439 or 90.35 per cent were cured. Mosaic warts with ill defined edges, which they have found radioresistant or unsuitable for close shielding, were not included. Otherwise the cases were unselected. Most of the warts had resisted other forms of treatment or they were recurrences. Many were fibrosed and their average duration was eleven months. A radical modification of the usual technic was employed. It consisted of a large predetermined initial

dosage, its size depending on several factors (size, depth, callus, keratitis and fibrosis), followed at intervals of ten days by one, two or three saturation doses of four fifths that of the initial dose, through precisely fitting shield holes in lead sheeting. These holes are reduced in size as the lesion shrinks. There were no reactions, pain, loss of time from work or any other unfortunate sequelae. Seldom have the authors irradiated a wart previously treated by others with radium or roentgen rays, for even if the total dosage given is known the size of the aperture through which the irradiations had been given is seldom definite.

Peptic Ulcer.—Dwyer and his associates review the 930 cases of duodenal ulcer and 103 cases of gastric ulcer encountered in a private clinic up to January 1939. In order to determine the progress of the patients with duodenal ulcer they sent out questionnaires to 238 patients who had been treated medically and surgically for ulcer from ten to twenty years before. Responses were received from 141 patients, 77 of whom had received medical and 64 surgical treatment. The average time since treatment had been fourteen years. Tabulation of the results for the 77 patients who had received medical treatment showed that 65 per cent considered themselves as having obtained 75 per cent or more relief of their gastric symptoms. Approximately one third (35 per cent) of the medically treated patients stated that they had obtained only 50 per cent or less relief of their symptoms and one half (56 per cent) of the patients with unsatisfactory results were later operated on. Pyloric obstruction developed in 6 per cent of the medically treated patients in an average of ten years. Of the 64 patients treated surgically, 86 per cent considered that they had received 75 per cent or more relief from their symptoms after operation. Posterior gastroenterostomy was done on 52 of these patients, and satisfactory results were obtained in 90 per cent; pyloric obstruction was the indication for operation in only 6 patients. The ulcer was excised in the remaining 12 patients and, after ten years, only one third considered the operation a success. Hemorrhage was recorded in 208, or 19 per cent of the entire series. Active hemorrhage

caused 113 of these patients to seek relief. Massive hemorrhage is more frequent before 45 years of age, but vital statistics show that only 4 per cent of patients dying of massive hemorrhage from peptic ulcer are less than 45 years of age. Early emergency operations for massive hemorrhage from ulcer in patients more than 45 years of age should save many lives. The highest incidence of duodenal ulcer is between 21 and 30 years of age; one third of the authors' patients began to have dyspepsia during this decade. The younger the patient at the onset of duodenal ulcer, the more characteristic are the symptoms. Patients less than 30 years of age who present gastric symptoms suggestive of peptic ulcer are more apt to have an ulcer than are older patients, especially those more than 40 years of age. The causes of reflex manifestations are considerably less frequent in younger patients than among older ones. Careful roentgen examination is the most important factor in diagnosing or excluding duodenal ulcer. Gastric ulcer is found in relatively older persons. The symptomatology of gastric ulcer often presents atypical and irregular disturbances, and these tend to be more severe than those associated with duodenal ulcer.

Management of Postoperative Wound Separation.—Fallis suggests that conservative nonoperative treatment be more widely adopted for treating disrupted abdominal wounds. A review of all the cases of such wounds at the Henry Ford Hospital up to and including the year 1935 gives the mortality rate of 34 per cent; 70 per cent of the patients who died did so within twenty-four hours of being subjected to secondary closure. It seems that at least in certain cases the operation itself was a determining lethal factor. Therefore alternative methods of management should receive serious consideration. Since 1936, 27 cases of wound disruption have been treated; they occurred among 4,153 laparotomies. The mortality rate was 37.3 per cent; but what is significant is the evidence in favor of nonoperative treatment. Seven of the 16 patients whose wounds were resutured died, a mortality of 43 per cent, but only 3 of the 11 whose wounds were strapped with adhesive tape died, a mortality of 27.3 per cent. Henceforth the author states that secondary suture has gradually been abandoned until, in the last two years, all disrupted wounds occurring in the general surgical service of the Henry Ford Hospital have been treated by packing and adhesive strapping, with excellent results.

Postoperative Shock Due to Hemolytic Streptococcus Wound Infection.—Stewart reports 4 cases which illustrate the syndrome of postoperative shock due to fulminating infection of the operative field with hemolytic streptococci. There was a delay of more than twenty-four hours after the onset of shock before wound infection was suspected. Immediate recognition is urgent, so that specific chemotherapy and immunotransfusion may be initiated early.

The Carrot as a Cause of Dermatitis. H. R. Vickers.—p. 52.

Sulfonamide Compounds and Lupus Erythematosus.—Barber suggests that lupus erythematosus may be of either tuberculous or streptococcic origin. When of the latter origin, sulfonamides (usually sulfanilamide) destroy the streptococci in the various foci and liberate toxin which provokes a complex reaction consisting of a rise of temperature, usually preceded by a rigor of varying intensity, generalized or localized pains in the fibromuscular tissues, a widespread scarlatiniform erythema, a focal reaction in existing patches of the eruption, reactivation of healed patches, appearance of new erythematous lesions continuous with or distinct from areas already affected, and painful swelling of lymph nodes. When the reaction has subsided, the eruption improves or disappears because of the diminished absorption of toxin or antigen. Although subsequent administration of the drug may be followed by an immediate and severe reaction, possibly owing to the remaining organisms being more vulnerable or accessible to it, the reactions tend progressively to diminish as the organisms are gradually destroyed. When a tuberculous infection was apparently responsible, the reactions did not occur nor was the eruption affected. The author believes that the reactions are due to the liberation of streptococcus toxin by the action of the sulfonamides on latent foci of infection and are not instances of drug fever.

Experimental Pigmentary Degeneration of Retina by Sodium Iodate.—Sorsby reviews clinical cases in which the use of septojod (a German iodine preparation containing sodium hypoiodite and sodium hypoiodate) led to transient or permanent loss of vision from pigmentary retinal changes. The author's experimental work and that of others leading to the incrimination of sodium iodate as the toxic agent is presented. The dosage for the experimental production of pigmentary degeneration of the retina in the rabbit is 5 cc. of 2 per cent solution injected intravenously. There is no evidence that with this dosage there is any permanent damage to other tissues, so that sodium iodate may be regarded as a selective poison for the retina. Vital staining (with Kiton fast green) has shown that the retina is damaged by iodate in the albino rabbit though no pigmentary disturbances are seen with the ophthalmoscope. Septojod has been used widely in German-speaking countries for septic conditions on the assumption that nascent iodine is liberated in the presence of septic material. It has been especially popular in the treatment of puerperal sepsis.

Placental Extract in Exanthematic Diseases.—Bassi employed placental extract treated with phenol for prevention of measles in 192 children. All but 4 proved to be immunized. Measles was mild in the 4 children who had it. One child who was not given the preventive injection because she stated that she had had the disease acquired it. The author administered this treatment to 7 young adults with scarlet fever, measles or varicella. The extract was given intramuscularly in daily doses of 4 or 5 cc. for three or four days. The course and duration of the disease were mild in all the patients. The author believes that placental extract is of preventive and therapeutic value in exanthematic diseases. The earlier the treatment the better the results. The treatment attenuates the disease and prevents complications.

Hepatic Cirrhosis and Hepatargy on Allergic Basis.—According to Schmengler's investigations the liver is involved in all processes which develop on the basis of a general allergic reaction. The symptom of this involvement can be demonstrated in a large percentage of cases of urticaria, Quincke's edema, rheumatism, serositis and polyserositis, asthma, acute glomerular nephritis, scarlet fever and some cutaneous diseases. Usually the hepatic damage is latent and without much significance. In some cases it is so pronounced as to overshadow all other symptoms. Since sensitization of the liver can be brought about by way of the portal circulation as well as by the systemic circulation, allergic injury of the liver can be caused by infectious foci as well as by disturbances in the gastrointestinal tract. Hepatic cirrhosis can be produced not only by alcohol but also by various toxins, which indicates that the development of this disease must also be possible on the basis of an anaphylactic reaction. It has been suggested that the so-called serous hepatitis might be the hitherto unknown first stage of hepatic cirrhosis. The author reports 2 cases which he regards as proof that hepatic cirrhosis might develop on the basis of an antigen-antibody reaction. The first patient was subject to hay fever and asthma. The hepatic impairment here was demonstrated by a severe disturbance in the galactose tolerance and a strongly positive Takata reaction. The second patient repeatedly developed severe urticaria after eating fresh fish. One severe and prolonged attack of urticaria was finally controlled by a strict diet. The patient then completely abstained from fish and was free from urticaria. Three weeks before the present hospitalization she had again eaten fish and on the following day she had a recurrence of urticaria, nausea and vomiting. Jaundice developed, and the skin had become a dark greenish yellow. The general condition became greatly impaired, and the patient died in coma. Necropsy disclosed cirrhosis. Nature has provided in these 2 cases more convincing proof than could be furnished by artificially induced experiments. Katsch once observed acute yellow necrosis of the liver following urticarial mani-

festations on the skin, but he failed to provide an explanation. The 2 cases reported here prove that serous hepatitis, latent liver damage, cirrhosis of the liver and hepatargy are a pathogenic and etiologic unit developing on the basis of a repeated allergic impairment.

*Thrombopenic Hemorrhages After Repeated Administration of Sedormid. H. Schäfer.—p. 1133.

Bechterew's Spondylarthritis Ankylopoietica.—Eltze reviews the pathologic anatomy and then describes the clinical picture of completely developed ankylopoietic spondylarthritis. Since early recognition is of great importance for effective treatment, he gives special attention to the incipient stages. The disease is sometimes preceded by rheumatic purpura or by nodose rheumatism of the scalp. An iritis may be the clinical sign of rheumatism. Neuralgias in the sciatic nerve, particularly if they are bilateral, and prolonged pain in the back make it advisable to resort to roentgenoscopy of the pelvis. This will frequently disclose changes in the sacroiliac articulation. The articular clefts are indefinite, and the articular surfaces appear as if gnawed on. Inflammatory niches are interspersed with narrow bone bridges, which gradually become wider. Cloudy densifications of the bone appear near the articular clefts. From one to three or even more years may elapse before these changes become visible in the roentgenogram. Limitation of the respiratory excursion likewise may occur early. The sedimentation speed of the erythrocytes is nearly always increased during the early stages. The rigidity of the vertebral column should make the observer think of ankylopoietic spondylarthritis. In the severe forms, complete stiffening and ossification take place within a few years or a decade and the patients become completely helpless. The benign form develops more slowly, in that two decades may elapse before the patient becomes incapacitated; the stiffening is usually not so severe in these cases. The atypical forms of ankylopoietic spondylarthritis are characterized by the fact that not only the large joints near the trunk (shoulder and hip joints) are diseased but also the more distal ones, that is, the elbow, hand, finger, knee and foot joints. Rheumatic heart disease may also exist. The recognition of the atypical forms is difficult because the clinical symptoms are often slight in spite of chronicity. However, if Bechterew's spondylarthritis ankylopoietica is thought of and sought, diagnosis is possible, particularly if the vertebral column is held rigid and the sacroiliac joint exhibits changes. To differentiate ankylopoietic spondylarthritis from spondylosis, it should be considered that spondylosis is due to wear and develops in persons of advanced age, whereas ankylopoietic spondylarthritis develops in the second or third decade of life although it may remain long unrecognized, so that it is not diagnosed until spondylosis causes the first complaints. Spondylarthritis ankylopoietica involves the entire or large portions of the vertebral column, whereas spondylosis is limited to a few vertebrae. There is no flattening of the physiologic lumbar lordosis, no increase in the sedimentation speed of the erythrocytes and no change in the sacroiliac joint in patients with spondylosis. The bridge formations on the vertebrae are thick in spondylosis, thin and shell-like in ankylopoietic spondylarthritis. The vertebral bodies are of glass-like transparency in ankylopoietic spondylarthritis, whereas their density is rather increased in spondylosis.

Thrombopenic Hemorrhages After Sedormid.—Schäfer reports the histories of 2 patients who developed thrombopenic hemorrhages after taking the hypnotic preparation sedormid (allyl-isopropyl-acetyl-carbamide). One case had a relatively mild course. In this case two tablets were necessary to elicit the symptoms, whereas in the other case a single tablet produced severe and prolonged hemorrhages and disturbances in

the general condition. The thrombopenic hemorrhages produced by sedormid usually terminate in complete cure, but if the physician does not know of the intake of this hypnotic he may diagnose a true thrombopenia. The author deplors the fact that sedormid in contradistinction to other, probably less harmful, barbituric acid hypnotics is obtainable without prescription. The author thinks that the firm marketing this hypnotic should at least be obliged to declare on the label the possibility of the development of hemorrhages of the skin and the mucous membranes.

Aspects of Diffuse Cerebral Sclerosis: Case of Familial, Late Infantile Type. O. Brandberg and E. Sjövall.—p. 131.

*Question of Ovarian Insufficiency in Mothers of Children with Mongolian Idiocy. H. Schröder.—p. 148.

Epileptic Aura. W. C. Weber and R. Jung.—p. 211.

Ovarian Insufficiency in Mothers of Children with Mongolian Idiocy.—Schröder studied sixty families in which mongolian idiocy occurred and obtained from the mothers detailed personal data on menstruation, the course of the pregnancy and birth of the mongolian idiot, gynecologic disorders and systemic diseases. After presenting the casuistics, he discusses such factors as belated menarche, disturbances of the menarche, persisting menstruation during pregnancy, disturbances in the menstrual cycle, ovarian and other gynecologic disorders, the menopause, signs of incretory disturbances and general diseases. Summarizing his observations he says that less than one fifth (11 of 60) of the mothers of children with mongolian idiocy had indications of an ovarian insufficiency in connection with the pregnancy resulting in the birth of the mongolian idiot. Control investigations on 60 mothers of normal children revealed similar disturbances in 18 cases at the time of conception or during gestation. Thus ovarian insufficiencies are of not more than average frequency in mothers of mongolian idiots. The author reaches the conclusion that Geyer's hypothesis, which ascribes the development of mongolian idiocy to the fertilization of ova the plasma of which had been impaired because of ovarian insufficiency in the mothers (dysplasmatic ova), cannot be corroborated.

*Influence of Deuteron-Deuteron-Neutron Rays on Blood Picture of Rabbits. H. Tatiiri and H. Ueda.—p. 35.

Deuteron-Deuteron-Neutron Rays and Blood Picture.—Tatiiri and Ueda report their observations on the changes in the blood picture of rabbits treated with deuteron-deuteron-neutron irradiation, which contains no gamma rays, and compare the effect thus obtained with that of radon-beryllium rays containing the gamma rays. The source of these radiations was the Nonaka modification of the Cockcroft-Walton apparatus, and the irradiation was given over the epigastrium of the animals for periods varying from five to sixty minutes at a distance of 10 cm. As a rule the principle effect of the irradiation was a significant diminution of white blood cells, a left shift of the pseudo-eosinophilic granulocytes and a particularly striking destruction of lymphocytes. Initial leukocytosis was observed in animals receiving irradiation for short durations (five to twenty minutes) but never in animals receiving longer intervals of irradiation (forty to sixty minutes). This constitutes proof of the fact that the neutrons, like other rays, obey the law of Arndt-Schulz. In comparison with the influence of radon-beryllium irradiation, the authors note one decided difference, namely that radon-beryllium irradiation exerts a much greater effect on the lymphocytes than does comparable amounts (millicurie units) of either the neutrons or the gamma rays from radon, but not more so than the combination of the two. This can mean only that the destructive effect of the radon-beryllium rays on the leukocytes results not merely from the simple summation effects of neutrons and gamma rays but from a complicated and synergistic effect of the two kinds of rays.

Opportunities for Surgeons in Medical Research

WARREN H. COLE, M.D.

CHICAGO

The most important opportunity, which, indeed, I would call an obligation and privilege, of the Society of University Surgeons is the participation in surgical research by its individual members. But first let me emphasize that I do not imply that every member must do research. It is well that our membership includes a variety of surgeons. Though surgeons have contributed much they have perhaps the rare and shameful distinction of having hardly a single society organized for the primary purpose of scientific investigation. The internists have two or three societies designed almost solely for the purpose of research; one of them, the Central Society for Clinical Research, benevolently maintains a small quota of their membership for surgeons. All of us are aware of the necessity for research in the progress of surgery. Since the membership of the society contains men all of whom are in the so-called age of research productivity, and since it is made up of men engaged in academic activities, it becomes imperative that we concentrate on research.

To emphasize still further the importance of research let me refer to some quotations by the physiologist Claude Bernard. With the exception of Pasteur, no man has been responsible for more rapid strides in medicine, in an equivalent length of time, than Bernard. The book he wrote in 1865 on *Experimental Medicine*, which was translated into English in 1927, is a masterpiece on the philosophy of research and cannot fail to inspire any of us. If you have not read it, I would urge you to do so. You will find it a splendid antidote for that depressed feeling which follows a day when all experiments go wrong and nothing seems to have been accomplished. There is one danger, however, which the reader must fight against in reading this volume: he must take care lest the brilliance yet simplicity of Bernard's reasoning inflict on him an inferiority complex. Bernard presented

medicine with so many illustrious advances only because he began his contributions early and persisted in his endeavors during even the latter days of his sixty-five years of life.

Early in his book it is obvious that Bernard wants it to be clearly understood just how important research is to progress in medicine; he remarked "Experimentation is undeniably harder in medicine than in any other science; but for that very reason it was never so necessary, and indeed so indispensable. The more complex the science, the more essential it is, in fact, to establish a good experimental standard, so as to secure comparable facts, free from sources of error. Nothing, I believe, is today so important to the progress of medicine." He repeats these thoughts, in different words, in many places throughout the book, thereby clearly indicating his belief in the importance of research work to medical science. He paid tribute to the great men of science by remarking that "It is in the darker regions of science that great men are recognized; they are marked by ideas which light up phenomena hitherto obscure and carry science forward." Yet he offered some slight solace to those of us outside the classification of great men by adding "Mediocre men often have the most acquired knowledge."

Although it is a well known fact that comparatively few men have the mental attributes to be successful research men, it is equally well known that men may be very intelligent without having the knack of being proficient in research. While originality is one of the most important attributes necessary, many additional characteristics indeed are required to produce men like Bernard and Pasteur. No more than two or three such geniuses will be encountered in any single century. There is great danger in attaching too much importance to originality, since a man with perseverance and industry, though lacking originality, is more apt to be productive (particularly if well guided) than a man displaying originality but lacking the tenacity to complete a long problem.

Part of the Presidential Address Delivered at the Third Annual Meeting of the Society of University Surgeons, St. Louis, Feb. 14, 1941.

Innumerable characteristics are therefore desirable and even necessary in the successful experimentalist. An astute power of observation is important indeed as exemplified by Bernard's story of his discovery of the relationship of the pancreas to fat digestion. He was operating on some rabbits while working on another problem when he discovered that white milky lymphatics were visible on the lower part of the duodenum beginning at about the point where the pancreatic duct emptied into the duodenum. More direct experiments dealing with the action of pancreatic juice on fats proved the suspected role of pancreatic juice in fat digestion. This experiment successfully illustrates how related or side problems may be much more important than the original problem. All of us have seen plenty of examples of this truth and in fact have had it happen to us. Unfortunately, these side problems can chase one up blind alleys at an amazing rate of speed, as most of us can again verify. Even the wary eye of a wild duck can be deceived by a dab of color properly placed on a wooden decoy. I hope none of you have been deprived of the pleasure of first hand experience in the demonstration of that phenomenon.

To get the most out of experimental work, one must at all times be an opportunist. Off-hand, we might think that none of us would fail to take advantage of an opportunity when encountered in our path. Yet the old master himself (Bernard) pays a kindly tribute to William Beaumont for having the foresight to turn circumstances to profit when Alexis St. Martin came to him with a hole in his stomach.

Failure to interpret results accurately is a frequent error and destroys the significance of many a problem. Too often indeed does the experimenter let coincidence lead him astray into fields of thistles and cactus. Bernard wrote that "coincidences form one of the most dangerous stumbling blocks encountered by experimental scientists in complex sciences like biology. It is the *post hoc, ergo propter hoc* of the doctors, into which we may very easily let ourselves be led, especially if the result of an experiment or an observation supports a preconceived idea." The latter mistake is equally important and common. Bernard consumes no less than thirty pages in condemning the habit of starting on the dangerous mission of proving a preconceived idea. Variations in results are the bugbear of all scientists. However, Bernard took pains to issue a warning as follows: "Nothing is accidental, and what seems to us accident is only an unknown fact whose explanation may furnish the occasion for a more or less important discovery." It was utilization of this philosophy that led Bernard to the discovery of the role of the liver in carbohydrate metabolism with conversion of glycogen to sugar and vice

versa. He found wide variations in his analyses of the sugar content of animals' liver; these variations consisted chiefly of higher readings several hours after removal of the liver from the body than at the time of removal. It was because he had faith in his analyses and repeated the experiments many times that he finally demonstrated without question the role of the liver in carbohydrate metabolism.

Scientists are continually being criticized for working on problems and issuing reports with doubtful value. Yet Bernard often makes the statement that there is no such thing as an unsuccessful experiment. He voiced my feelings exactly in his remarks, which cannot be improved on: "I therefore refuse to acknowledge that science has a place for men who make criticism their specialty, as in letters and in the arts. To be really useful, criticism in every science must be done by men of science themselves, and by the most eminent masters." In other words, no one knows at what time certain seemingly trivial data may be picked up by an opportunist and crystallized into an epoch making discovery by utilizing some additional data. After all, does it not seem a far cry from Dam's experiments on a bloody diarrhea in chicks, or Roderick's demonstration of hepatic disease in sweet clover disease of cattle, to the development of vitamin K? Perhaps it does, yet these two insignificant experiments gave rise to the dramatic and useful discovery of prevention of hemorrhage in jaundice. All of us, when we stop to think, can recall to mind many such instances when major discoveries were made possible by some trivial, seemingly insignificant, experiment.

Medical scientists fully realize that animal experimentation is a much better medium for development of important data than a flock of test tubes and inorganic bodies. It is likewise granted that the human being is a much better guinea pig than the four legged genus *Cavia porcellus* himself. We must realize, however, that while we are finding 8 or 10 patients with the proper symptom complex we might have completed a hundred or more experiments on animals, thereby tending to eliminate the statistical error of the time worn apology "a small series." Moreover, we must constantly ask ourselves that simple question Are my experiments jeopardizing the patient's health or chance of recovery? Again, Bernard touched the crucial point when he said "The principle of medical and surgical morality therefore consists in never performing on man an experiment which might be harmful to him to any extent, even though the result might be highly advantageous to science, i. e., to the health of others. But performing experiments and operations exclusively from the point of view of the patient's

own advantage does not prevent them turning out profitably to science."

The young ambitious medical scientist, more saturated perhaps with the vision of glory than with the persevering, analytic astuteness of a seasoned scientist, may in desperation and disgust say "Why work any more; all discoveries of importance have already been made?" Of course, we are all aware of the fallacy of that remark and realize that the addition of scientific facts as compiled year after year increases the chances of development of epoch making discoveries in a geometric ratio. True enough, the chances of making epochal discoveries in the mechanics of operative principles are being diminished; not so though with the physiologic principles involved in operations. Still more fruitful are the physiologic principles which can be utilized for the patients' welfare before or after operative procedures are performed.

As all of us fully realize, the benefits derived from the practice of medicine or surgery may be threefold: (1) personal satisfaction or happiness, (2) financial reward and (3) creation of

an enviable professional reputation. All of the peers and seers of medicine as far back as the hippocratic era remind us of the serious accusations hurled at the monetary instinct. It is axiomatic that indeed few surgeons of the academic group (exemplified by this society) chose that path for the monetary compensation obtainable. Naturally, they elected to spend the majority of their time in institutional work for the personal satisfaction derived from work itself or the reputation created. I have no doubt that all the members of this audience are well aware of the curious fact that the short cut to an enviable national reputation lies in the corridors which traverse the halls of experimental medicine and surgery. The esteem of one's fellows, beyond his local environs, can be achieved in about half the time required by concentration on purely clinical medicine or surgery. It is likewise self evident that because of his lasting contributions to mankind this type of doctor will always be in demand. May his kind flourish and prosper!

1853 Polk Street.

The Function of the Museum in the Medical School

WILLIAM BOYD, M.D.

Professor of Pathology and Bacteriology, University of Toronto
Faculty of Medicine
TORONTO, CANADA

Various types of museums find their place in the medical school. The chief of these are the anatomic museum and the pathologic museum. It is with the latter that this paper deals. I should prefer, however, to refer to it as the medical rather than the pathologic museum, because the latter term suggests a series of specimens in bottles, and the museum should be very much more than that.

The old museums were storehouses for pickled specimens, and such great collections as those of the German universities, the London hospitals and the Royal College of Surgeons in London and in Edinburgh played a great part in their day and still do so. But the modern tendency is to make things easier for the student, which can best be done by making them more interesting. This can be accomplished by presenting more than one aspect of a subject and by presenting the subject in as attractive a manner as possible. Those who visit the great Army Medical Museum at Washington will see both of these principles put into practice, and the scientific exhibits at the meetings of the American Medical Association are a striking demonstration of the drawing power of perfectly arranged displays.

I have had the experience of converting two of the classic forms of museum into something

more modern in type, the one in Winnipeg, the other in Toronto. The basic principle underlying the work was the same in the two instances, but there was one difference worth noting. In Winnipeg the museum, as is commonly the case, consisted of one large room (although later a second was added), whereas in Toronto there was a large number of small rooms, one for the circulatory system, one for the nervous system, and so on. The convenience of the latter arrangement for teaching a number of groups is self evident.

The aim has been to make a clinicopathologic museum, a museum depicting disease in all its aspects. This is done by displaying, in addition to the gross specimens, illustrations of clinical conditions, microscopic appearances, roentgen ray findings, temperature charts, blood pictures, and so on. Nor is the historical side of medicine neglected. A few examples will illustrate the general idea. In the section on Addison's disease, in addition to the lesions of the adrenals there is a water color painting of a patient showing the characteristic bronzing of the skin, another of the pigmentation of the mouth and tongue, and a picture of Thomas Addison with a short biographic sketch. Exophthalmic goiter is illustrated by a picture of a patient with exophthalmos and enlarged neck, gross specimens of the thyroid, the microscopic picture and a representation of Robert Graves with biographic

Read before the joint meeting of the Council on Medical Education and Hospitals and the Federation of State Medical Boards of the United States at the Thirty-Seventh Annual Congress on Medical Education and Licensure, Chicago, Feb. 18, 1911.

notes. The section on glomerulonephritis is illustrated by a picture of Richard Bright, plates from Volhard and Fahr's classic monograph, a painting of the fundus showing albuminuric retinitis, and Oliver's reconstructions of the nephrons in chronic nephritis.

Instead of multiplying these examples endlessly, I will mention some details of the methods of display. One fundamental principle has been observed, namely that it is more restful to study a specimen when it is inclined than when it is upright. For this reason the ordinary museum display cases with horizontal shelves have been replaced by open stands of sloping shelves. There are five tiers of these shelves, and the whole fixture is painted white. The classic glass museum jars are not suitable for the narrow ledges which separate these shelves, but watch glasses of various sizes are admirably adapted to this purpose, as also are narrow glass cells which can be readily made by the technician. Both of these are much cheaper than the glass jar.

On the wall above the display stand there is a wooden board which serves to carry the various pictures. These illustrate the specimens on the shelves beneath. Attached to the lowest shelf there is a narrow box containing cards 7 by 8 inches in size. These are of sufficient size to contain a condensed copy of the catalogue description; indeed they replace the former catalogue. The back of the card can be used for a photomicrograph of the lesion, the whole being covered with hexoid and bound with fiber reinforcing tape. The advantage of this arrangement is that the student can sit down, study the specimen and read the description without having to move.

Pictures are of special value in the large room devoted to general pathology. Colored illustrations of the various fat, glycogen and amyloid stains recall to the student what he has seen or should see through the microscope. The inclusion bodies of virus diseases can be collected to form one composite picture. Another such picture shows the life cycle of the malaria parasite in man and in the mosquito, the anophelines mosquito compared with the culex, the temperature charts of tertian and quartan fever, the parasites in the brain and the pigment in the spleen. A third shows a map indicating the geographic distribution of trypanosomiasis, the trypanosomes in the blood, the tsetse fly, the lymphadenopathy and the native lying in his hut in the last stages of stupor. Colored illustrations of the rashes, mucous patches and condylomas of syphilis are surely as instructive as specimens of gumma and are absolutely necessary to complete the picture of the disease. There are hundreds of beautiful colored plates hidden away in atlases which remain unopened for years on library shelves. The best use to

which an atlas can be put is to have its pictures torn out and displayed.

A feature of psychologic value is the use of the principle of what may be called paragraphing. In the bone room, for instance, the main disease groups such as osteomyelitis, tuberculosis and tumors are separated from one another by broad vertical strips of black cellophane. The individual members of such a group as bone tumors (osteogenic sarcoma, Ewing's tumor and others) are separated by thin green strips. The main groups are indicated by large labels on the wall, the subgroups by smaller labels at a lower level. This paragraphing not only makes it easy to find all the specimens of any given disease but enables the observer to carry away a visual memory of any particular group in which he may be interested.

In each of the small rooms a large viewing box is installed, which can be used for roentgenograms or transparencies of photomicrographs, clinical pictures or paintings of blood films. This box is deep enough to accommodate half a dozen wooden frames, each large enough to carry twelve 5 by 7 inch reductions; it is high enough so that all the frames can be pushed up out of sight above the limits of the glass. In the lung room one frame is devoted to tuberculosis, one to suppurative conditions, one to tumors, and so on. Whichever one is wanted is pulled down, so that the films are in front of the illuminated glass.

It will be evident that this type of museum is designed for the teaching not only of pathology but also of medicine and surgery, for it is a museum of disease and not merely of pathologic specimens. It is for the use not only of undergraduates but also of graduates and especially of those preparing themselves for the higher examinations. It is a museum of which it may be said that it is "a library composed, not of books, but of the things themselves about which books are written."

Medicine Antedates the Inception of Civil Law.—Medicine is the most ancient of professions, being older than Christianity and antedating the inception of civil law. It has its own system of rewards and punishments, its own disappointments and its own glories. It is a profession that has a broadening influence on the human mind and is characterized by a most splendid charity. It is an acquisition in the best tendencies and a protection against the worst tendencies. It retains for its profit no valuable discovery and it has no standing room for the quack, the scoundrel and the charlatan. Its best work is done in the light which beats upon its throne, not in the arena of politics encouraged by the cheers of thousands, not in the seclusion of the cloister sustained by the hope of eternal joy, but in the storm and wind swept country, in the streets of the village, in the boulevards of the city, on the desolate field of battle, where pain and pestilence, illness and misery are combated often with none but God to see it. It furnishes a curiously checkered life, a life in which storm clouds alternate with sunbeams.—Abell, Irvin: *The Spirit of Medicine, Pharos of Alpha Omega Alpha*, May 1941.

Digests and Reviews

TUBERCULOSIS AMONG STUDENTS AND GRADUATES OF MEDICINE

Abstract of an article by J. A. Myers, H. S. Diehl, Ruth E. Boynton, P. T. Y. Ch'in, T. L. Streukens and Benedict Trach in the Annals of Internal Medicine, March 1941.

We have attempted to trace the 1,894 medical students who graduated or were scheduled to graduate from the University of Minnesota from 1919 to 1936 inclusive. Group 1 includes 1,441 students in the graduating classes from 1919 to 1932 inclusive, and group 2 includes 453 students in classes graduating from 1933 to 1936. Prior to 1929 no special routine examination for tuberculosis was made of students. Consequently information on group 1 was obtained largely through questionnaires. Information concerning 7.5 per cent of the entire group was not obtained.

GROUP 1

There were 1,304 replies from the members of the classes of 1919 to 1932. Forty-one (3.14 per cent) stated that clinical tuberculosis developed while they were in school. Ten others reported having had pleural effusions as students and 5 others that they had tuberculosis before entering medical school. Also 41 of the remaining 1,248 graduates (3.29 per cent), including 4 with pleural effusion, reported that tuberculosis developed in them after graduation from medical school. Thus, exclusive of the 5 who had tuberculosis before entering medical school 92 (7.07 per cent) have had the clinical disease while in school or since graduation. Of these, 11 (0.85 per cent) have died of tuberculosis.

Concerning tuberculin reactions, 389 have either had no tests or do not remember the results. Reactors to tuberculin varied from 15 to 33 until 1925, whereas the percentage of graduates who either had no tests or did not remember varied from 46 to 62 during this same period. In 1925 a tuberculosis service was made compulsory and in 1929 routine annual testing of all medical students was begun. The number reporting reactions has risen sharply since then, while the number who were not tested or do not remember has shown a sharp decrease. The 1932 class recorded 85 per cent reactors and only 3 per cent with no tests.

GROUP 2

The 453 students who entered the School of Medicine from 1929 to 1932 inclusive were carefully examined throughout their enrolment. The entire class entering in 1929 was tested with tuberculin and had annual roentgenograms of the chest regardless of the tuberculin reaction. The nonreactors on entrance were retested annually unless they became reactors. The

members of the other three classes had tuberculin tests on entrance and annually or more often as long as they were nonreactors. Four of the 453 have died of nontuberculous diseases, leaving 449 students.

The percentage of reactors in these classes ranges from 33.3 to 37, while on graduation the percentage is from 57.7 to 77.9. The average in the four classes is 35.6 per cent on entrance, 41 per cent at the end of the third year and 67 per cent at the end of the fourth year, and 50.2 per cent of those who reacted negatively on entrance became positive before graduation. While there was an increase of reactors between entrance and the end of the junior year, the increase was greater during the senior year. Of the 449 students, 160 reacted to the test on entrance, 145 became reactors while in school and 144 were nonreactors on graduation.

Replies have been received from 369 of the 449 graduates. Of these 102 were from physicians who did not react to tuberculin at the end of the senior year. Sixty-five of these have had tuberculin tests since graduation, 30 of whom became reactors as interns, 15 following their internships and 20 are still nonreactors.

Although few of these graduates interned at hospitals requiring tuberculosis services, practically all were exposed to the unsuspected contagious case of tuberculosis admitted for some other coexisting condition. Moreover, most of these hospitals do not examine the members of their own personnel. To allow 46.2 per cent of uninfected interns to become infected during their hospital services constitutes a serious problem in tuberculosis control. From our observations among these physicians while they were students, together with their replies to our questionnaires, we now know of 350 (78.2 per cent) who react to tuberculin.

Students in the College of Education, the control group, came from the same general section of the country and while in school lived in the same general environment as the students of medicine except that they were not brought in direct contact with tuberculous patients as a part of their work. On entrance to the College of Education 24.8 per cent of the students reacted to tuberculin, while on graduation the percentage was 28.5. Thus, only slightly more than 1 per cent of the nonreactors became infected each year.

On entrance to the School of Medicine there were 160 students in the classes of 1933-1936 who had primary complexes as manifested by the tuberculin reaction. Five of these students are known to have since had diagnoses of clinical tuberculosis, a percentage of 3.1 as compared to 0.41, or 3 among 686 reactors from the Col-

lege of Education students. Of the 145 students in group 2 in whom the primary tuberculosis complex as manifested by the tuberculin reaction developed while in school, 14, or 9.6 per cent, have had lesions demonstrated as against the 3 among the College of Education students. However, 4 of the 14 had evidence only of primary foci located by roentgen study, 5 had only pleurisy with effusion, extrapulmonary clinical tuberculosis developed in 1, and clinical pulmonary disease developed in 4. The remaining 131 would not have known of the tuberculosis had it not been for the periodic tuberculin test.

Five of 45 students who replied to our questionnaire and stated that they had become tuberculin reactors since graduation have shown evidence of lesions on roentgen examination. Thus among the 305 students of medicine who were tuberculin reactors on entrance or who became reactors while in school, lesions which were located by roentgen or other methods of examination have developed in 18 as against the 3 in a total of 686 College of Education students who reacted to tuberculin either on entrance or subsequently. Neither in the School of Medicine nor in the College of Education do we know of any one in whom tuberculosis developed in the absence of a tuberculin reaction.

This study emphasizes, in addition to the hazards of exposure, the fact that the entire span of life must be considered in every case of tuberculosis whether the diagnosis is made by the tuberculin test alone or together with the demonstration of the location of lesions. In these students we have seen the evolution of tuberculosis: the history of exposure, the first tuberculin reaction, occasional location of the primary focus on roentgen examination and the reinfection type of lesions in the lungs. The procedure carried out in group 2 represents our future course in tuberculosis control.

PULMONARY TUBERCULOSIS IN MEDICAL STUDENTS

Abstract of an article by Richard G. Hahn, Carl Muschenheim and Jules Freund, published in the American Review of Tuberculosis, May 1941.

The present communication is a report of the results of tuberculosis case finding applied to groups of medical and nursing students at the Cornell University Medical College and the New York Hospital.

The methods employed were the intracutaneous tuberculin test and the roentgenographic examination of the chest. The reactions were read two days after the intracutaneous injections and were considered positive if the skin was raised over an area of a diameter of 5 mm. or more. The roentgenograms of the chest were made in the roentgen ray department of the hospital with standard technic, single postero-

anterior views being used. Tests were made on first year medical students and student nurses within two months of admission to their respective schools and during the last month of their final year.

RESULTS WITH MEDICAL STUDENTS

Six first year classes were tested. The percentage of positive reactors varied from 75 to 89. Collectively, of the 315 first year students tested 259, or 82.2 per cent, were positive and 56, or 17.7 per cent, were negative. Fourth year classes graduating in 1935, 1936 and 1937 were similarly examined. Of the total of 147 tested 135, or 91.8 per cent, were found positive and 12, or 8.1 per cent, were negative. The incidence of positive reactors in the fourth year classes tested was thus 9.6 percentage points higher than in the first year classes. The percentage of negative reactors shortly before graduation in both the medical and nursing student groups has varied in different years from zero to 14.3. The average for the nursing student (of the classes of 1933 to 1939 inclusive) has been 6 per cent negative on graduation and, for the medical students, 8.7 per cent.

CHEST ROENTGENOGRAPHY

The medical students have had yearly roentgenograms of the chest since 1934. A total of 442 students each had at least one roentgenographic examination. Seventy-one, or 16.1 per cent, had calcified deposits in the tracheobronchial lymph nodes, in the pulmonary parenchyma or in both. These were interpreted as healed lesions of the childhood type. In 22, or 5 per cent, there were shadows at either or both of the extreme apexes of only several millimeters thickness. These were interpreted as thickening of the apical pleura with possibly some parenchymal involvement. This group was classified as doubtful. The calcified shadows and the doubtful apical shadows were found in every instance in the student's initial roentgenogram. None appeared in subsequent roentgenograms of those whose original film had been entirely negative. There was also no instance in which these shadows changed during the period of observation and, incidentally, no student whose initial film revealed either type of shadow was in the group in which definite pulmonary infiltrations developed later. Five, or 1.1 per cent, had shadows characteristic of chronic pulmonary tuberculosis in the initial roentgenogram. The lesions were all minimal in extent. Only 2 of the 5 were found in the first academic year. The other 3 belonged to the classes of 1934 and 1935, which were not roentgenographed until their fourth and third years, respectively. Four other students, or 0.9 per cent, who had been negative in their initial

roentgenographic examination developed shadows characteristic of chronic pulmonary tuberculosis in subsequent years. Three were minimal and one was moderately advanced when found. None had complained of any symptoms before the lesion was discovered. In addition to having shown no roentgenographic evidence of tuberculosis, 3 of the 4 had originally been negative to 1 mg. of tuberculin. These 9 students, 2 per cent of the total, who were discovered to have chronic pulmonary tuberculosis, represent the entire number of cases found, including the apparently arrested as well as those in which progressive disease was demonstrated. Four of the 9 had lesions which were obviously progressive and these students were referred to sanatoriums immediately after discovery of the disease. The other 5, for various reasons not under our control, were allowed to continue at work and complete their course. Of these there were only 2 in regard to whom we possess subsequent information sufficient to determine whether their disease was arrested at the time of discovery. One of these has never had any symptoms or physical signs attributable to his lesion, which has remained unchanged in serial roentgenograms over a period of four years. The other is known to have had progression of his disease since graduation. The average age of all the students on entrance to the medical school was 22.

The tuberculosis rate in the medical students does not appear to be significantly above the expected rate in their age group. The rates both in the nursing and in the medical students are considerably below those reported in some other institutions of similar nature. Whether the relatively low incidence of pulmonary tuberculosis in the student groups is due entirely to rather rigid precautions is problematic. That the students are not completely protected from new infections, whether acquired within or

without the hospital, is evident from the increase in the number of positive tuberculin reactors in successive years. Other factors which we think may contribute to the low rate of development of new lesions, at least in reference to the nursing students, are the conditions of housing and of nutrition which we believe to be exceptionally good, and the age of the students, who are somewhat older than in many other training schools. A high percentage of positive tuberculin reactors in our medical and nursing student groups on admission may indicate that most of them had a considerable degree of acquired resistance. Our experience would tend to support the observations of others that the students who are originally tuberculin negative are more likely to develop clinically significant disease than those originally tuberculin positive.

The incidence of pulmonary tuberculosis, inclusive of cases with arrested disease, was found to be 2 per cent for the medical students and 1.1 per cent for the nursing students. The incidence of new lesions developing after the initial roentgenographic examinations of entering students was 0.35 per hundred annually among medical students and 0.18 per hundred annually among nursing students.

It is our impression that asymptomatic tuberculosis in young adults eventually progresses in the majority of instances and should always be treated early. A definite policy, therefore, has recently been followed of recommending prompt treatment for all patients under 30 years of age in whom an infiltrative lesion has been discovered, regardless of the presence or absence of symptoms, the extent of the lesion or the results of sputum examinations and other laboratory procedures. We regard lesions presumed to be primary or first infection type as of as serious significance as those which appear to be the result of endogenous or exogenous reinfections.

Correspondence

SIGNERS OF THE DECLARATION OF INDEPENDENCE

To the Editor:—Dr. Ward called attention in the Student Section of THE JOURNAL, March 22, page 1331, to physician signers of the Declaration of Independence. However, the name of George Taylor, representing Pennsylvania, should not be included among them, as there is no evidence to this effect. The statement in the 1913 edition of Funk and Wagnall's "New Standard Dictionary" that he was a physician is apparently incorrect and was withdrawn from later editions. There is no mention of his being a physician in Kelly and Burrage's "American Medical Biographies," in F. R. Packard's "History of Medicine

in the United States" or in the "Dictionary of American Biography" (Scribners, New York). In John Sanderson's "Biography of the Signers of the Declaration of Independence," to be sure, it is stated that Taylor commenced the study of medicine but soon became disgusted with it and, according to the Bucks County Historical Society publications, "ran away from home."

I quite agree with Dr. Ward that the medical profession should know more medical history, and I hope that he will agree with me that, as such history should be as accurate as possible, even this small point deserves correction.

E. B. KRUMBHAR, M.D., Philadelphia.

DO YOU KNOW WHAT PHYSICIAN—

1. Discovered the parasite of malaria fever?
2. Became Poet Laureate of England?
3. Wrote "Rab and His Friends"?
4. Was the pioneer in the graphic study of cardiac arrhythmias?

DO YOU KNOW WHAT ANATOMIST
5. Painted what is considered to be the most famous portrait in the world?

DO YOU KNOW WHAT ZOOLOGIST
6. Discovered the cause of syphilis?

The answers are on page 2552.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items for consideration for publication in the Student Section.

Rush Medical College to Merge with Illinois

The board of trustees of Rush Medical College, Chicago, has asked the attorney general of the state to prepare a court petition for dissolution of the ties of Rush Medical College with the University of Chicago in preparation for a merger of its educational elements with the University of Illinois College of Medicine. The question is now before the circuit court. The newspapers reported, May 3, that these proposals are the result of long and extensive negotiations with the board of the Presbyterian Hospital and representatives of the medical and fiscal divisions of the two universities. Presbyterian Hospital is the teaching hospital for Rush Medical College, and members of its staff are all instructors at the college. The proposed plan is (1) severing of affiliation with the University of Chicago which has been continuous since 1924, and (2) abolition of Rush Medical College as an educational institution but retention of the Rush board to administer the physical properties of the college. Subdivisions of this main plan call for the absorption of all Rush medical instructors into the University of Illinois College of Medicine and affiliation of the Presbyterian Hospital with the state university's medical department. The Rush name will not be lost under the setup in that the Rush teachers will be known as Rush professors of the University of Illinois College of Medicine. The Rush buildings will be leased to the hospital for expansion purposes and possibly as instruction rooms for the medical students at Illinois. At this time there are about two hundred undergraduates in Rush Medical College in the junior and senior classes. The University of Chicago has agreed, according to the program, to graduate the junior class, but no more students will be accepted by Rush and the 1942 class will be its last. There will be no graduate school at Rush as once was planned. The Central Free Dispensary, which is operated in cooperation with Rush Medical College, will be taken over as an outpatient hospital consolidated with Presbyterian Hospital, with the hope that the dispensary and the hospital can have identical boards of trustees.

Loan Funds at Alabama

Students in the University of Alabama School of Medicine, University, maintain two loan funds, a fund for the purchase of library material pertaining to medical history, ethics and economics and a fund to provide a speaker each year in honor of Dr. William Crawford Gorgas. The Library Fund is known as the Freshman Memorial Library Fund and was established during the session of 1928-1929. Contributions are made voluntarily by practically all members of the freshman class. The librarian and the dean, ex officio,

and two members of the faculty administer the fund. During the past decade more than six hundred volumes have been purchased, the *Annals of Medical History* subscribed for and portraits of James Marion Sims, John Y. Bassett and John Wyeth, all famous Alabama physicians, secured.

The James Marion Sims Loan Fund was spontaneously founded last year by voluntary subscriptions of the freshman class, varying in amounts from 50 cents to \$35. The present freshman class has followed the procedure established last year. The professor of anatomy and the dean of the school, with a certified public accountant from the commerce faculty, have been named trustees of the fund.

The other loan fund in the medical school was established last year by the Sigma chapter of Phi Beta Pi Medical Fraternity. This fund is administered by a faculty committee of five with the dean as ex officio secretary and treasurer.

In addition, Alpha Epsilon Delta, premedical fraternity, sponsors an annual program in association with the medical school, and this society last year also established the Alpha Epsilon Delta Loan Fund with the chapter's faculty adviser, an associate professor of biology, and the dean of the medical school, ex officio, with the same professor of accounting from the School of Commerce as the third member. All three funds are audited by a certified public accountant annually and reports made to the donors.

The Gorgas Medical Society consists of all students in good standing enrolled in the school after the first semester. All members of the society and members of the faculty contribute \$1 each with which a speaker is secured annually in honor of the birthday of Dr. William Crawford Gorgas of Alabama. This year Prof. Anton J. Carlson of Chicago will be the speaker. The Gorgas Medical Society in the school chooses annually a limited number of the sophomore class as Gorgas fellows. This is the highest honor awarded during the session.

Oklahoma Seniors Apply for Commissions

Twenty members of the senior class of the University of Oklahoma School of Medicine, Oklahoma City, have applied for commissions in the Medical Reserve Corps of the U. S. Army. The commissions are being granted by the War Department, our correspondent states, with the understanding that these young physicians will not be called into actual military service until after completing one year's internship following graduation.

A plaque in honor of the late Dr. Leroy Long, dean of the University of Oklahoma School of Medicine for many years, was dedicated by appropriate ceremonies in the auditorium of the school May 19. The plaque

was erected by the Oklahoma State Medical Association and the alumni association of the medical school and was modeled by Joseph R. Taylor, associate professor of art at the university.

Pennsylvania's Annual Undergraduate Meeting

At the thirty-third annual meeting of the Undergraduate Medical Association of the University of Pennsylvania, the opening address, by Dr. John H. Stokes, was "The Young Doctor and the War." Dr. Cornelius P. Rhoads, New York, of the Rockefeller Institute for Medical Research and director of the Memorial Hospital for the Treatment of Cancer, spoke on "Chemical Aspects of Cancer," and A. Baird Hastings, Ph.D., Hamilton Kuhn professor of biological chemistry, Harvard University, Cambridge, Mass., on "The Case for the Intracellular Fluid." Papers on research were presented by nine students. The May Ellis Bell Prize was presented to Christian J. Lambertsen '43 for his paper on "A Diving Apparatus for Life Saving." The John G. Clark Prize was awarded to John C. Lilly '42 for his paper on "The Electrical Capacitance Diaphragm Manometer: A New Apparatus for Direct Blood Pressure Determination." The Grahye Simpson Priestley Prize was awarded to Martin G. Netsky '43 for his paper "Some Effects of Desoxycorticosterone and Related Compounds on the Mammalian Red Cell." Miss Lillian B. Panzer '44 was given honorable mention for her paper on "Experimental Hypoprolthrombinemia."

California's Gold Headed Cane

At the annual gold headed cane ceremony at the University of California Medical School, San Francisco, April 14, Robert H. Crede, a senior student, received the award. The guest speaker on this occasion was Dr. George Blumer, professor of medicine at Yale University School of Medicine, New Haven, Conn., who also was awarded a gold headed cane. A cane is given annually to the member of the senior class who is adjudged most likely in the opinion of his classmates and the faculty to be eminently successful in the profession. This ceremony is adopted from an old English custom in which a single gold headed cane was handed down through generations of eminent British physicians.

New Indiana A. O. A. Members

The following upper classmen at Indiana University School of Medicine, Bloomington, have recently been elected members of A. O. A. honorary scholastic society: Wallace E. Bash, Warsaw; Margaret Ann Bassett, Thorntown; Mary H. Beall, Rushville; Otis R. Bowen, Crown Point; Lawrence A. Cantow, New York; Jack Dick, Huntington; Laura Hare, Indianapolis; Edgar A. Hawk, New Palestine; John E. Heubi, Jeffersonville; Joe Humphreys, Cloverdale; Joe H. Jewett, Carmel; William W. Kriebel, Terre Haute; Griffith Marr, Columbus; Charles F. Martin Jr., Logansport; Sherman Minton Jr., New Albany; Theodore F. Schlaegel Jr., Indianapolis; Lawson F. Smith, Indianapolis, and James B. Warriner, Indianapolis.

Harvard Awards Christian Prize

John William Raker, a fourth year student, has been awarded the Henry A. Christian prize at the Harvard Medical School, Boston, which is given to a student in the senior class "who has displayed diligence and notable scholarship and offers promise for the future." Mr. Raker, who is from Kutztown, Pa., graduated from Bucknell University in 1937. The award was established a few years ago in honor of Dr. Henry A. Christian, professor of theory and practice of physics, emeritus.

Dr. Brücke Goes to East Indies

The fourth year students at the University of California Medical School, San Francisco, were recently addressed by Dr. Ernst T. von Brücke, of the physiology department of Harvard Medical School, Boston, who was en route to the Dutch East Indies, where he will engage in surgical work for the Dutch army. Dr. Brücke lectured on his surgical experiences with a Red Cross unit sent by the Netherlands to Ethiopia a few years ago and recently to Finland.

Among the seminars conducted recently at the medical school on the early medical history of California was one conducted by Dr. John B. de C. M. Saunders on "Chacon Daza, Author of the Earliest Textbook of Surgery on the North American Continent."

The Contin Society

Dr. Arthur Fishberg delivered the first annual lecture of the Contin Society, an honorary organization at the New York Medical College and Fifth Avenue Hospitals, New York, May 9, on "Recent Developments in Essential Hypertension." Dr. Samuel J. Kopetzky, chief of the medical division of Selective Service of the City of New York, addressed the annual induction meeting of the Contin Society, February 6, on the draft in relation to doctors, interns and medical students. The following students were inducted into the society: seniors—Milton Willner, Sidney Cramer and A. Winifred Phillips; juniors—Letizia Ciaramelli, Theodore Struhl, Thomas Benson and Abraham Uman-sky. The faculty members elected to honorary membership to this society were Dr. J. A. Werner Hetrick, acting dean and head of the department of otolaryngology; Dr. Reuel A. Benson, head of the department of pediatrics, and Dr. Milton J. Raisbeck, associate professor of medicine.

University of California Charter Day Exercises

Students, faculty and alumni attended Charter Day exercises held in San Francisco, March 28-29, at the University of California Medical Center to celebrate the university's seventy-third birthday. The dean of Stanford University School of Medicine, Dr. Loren R. Chandler, spoke on "The Future of the Student and Recent Graduate." The celebration included clinics, demonstrations at the medical school, the annual meeting and the banquet of the medical alumni, at which Dr. Karl F. Meyer, professor of bacteriology, discussed "The Relationship of Public Health to National Defense."

Undergraduate Meeting at George Washington University

One day in the year is set aside for an undergraduate medical meeting at the George Washington University School of Medicine, Washington, D. C.; the second annual meeting of this kind was held at the medical school April 19. The morning of that day was devoted to the presentation of seventeen papers by students who have been engaged in research. In the afternoon the student body was addressed by Dr. Nicholson J. Eastman, professor of obstetrics, Johns Hopkins University School of Medicine, Baltimore, on "Asphyxia Neonatorum." In the evening the first annual medical ball was held at the Shoreham Hotel.

Medical History at Long Island

A group of students at Long Island College of Medicine, Brooklyn, have formed a medical history club under the tentative name of Donellon House Club. At the first meeting, February 26, among other subjects

presented was "Sammelweis and Puerperal Sepsis" and "Medicine in Old London." At the second meeting, April 17, Jean A. Curran, dean of the medical school, presented a paper entitled "An Unknown Genius of American Medicine" (John Shaw Billings).

New Yale Members of A. O. A.

The Yale chapter of Alpha Omega Alpha, medical honorary society, announced on May 15 the election of the following medical students to membership in the society: Gioacchino S. Parrella, New Haven; Irving Waltman, Hartford; James M. Bunce, Hartford; Allan V. N. Goodyer, Stamford; John R. Lincoln, West Hartford; Maurice Tulin, Hartford; Antonio J. Waring Jr., Savannah, Ga., and Irving N. Wolfson, New York. Dr. Arnold L. Gesell, director of the Clinic of Child Development of Yale University, was elected an honorary member. Following the banquet and initiation, which was held in the Yale Faculty Club, Rudolf Schoenheimer, associate professor of biochemistry at Columbia University, New York, gave the annual Alpha Omega Alpha lecture on "The State of the Structural Elements of Life."

Premedical Fraternity at Detroit

The national honorary premedical fraternity, Alpha Epsilon Delta, installed its thirty-second chapter at the University of Detroit, Michigan, March 8, 1941, when the Iota chapter of Omega Beta Pi became the Michigan Alpha chapter of Alpha Epsilon Delta with the induction into the fraternity of twenty students and two faculty members.

Woman's Medical College

The third and fourth year students of Woman's Medical College of Pennsylvania, Philadelphia, were addressed, January 2, by Dr. Bertha Van Hoosen, of Chicago, on "Surgery Made Plain." The lecture forum of the college presented a symposium on "Chronic Cumulative Lead Intoxication," February 14; the speakers were Dr. Helena E. Riggs and Messrs. Feodor Letonoff and John Reinhold.

The Marion Sims Society

The first of a series of annual lectures, sponsored by the Marion Sims Clinical Society of the Medical College of the State of South Carolina, was given at the college at Charleston, April 25, by Dr. James H. Gibbes of Columbia, S. C., whose subject was "Marion Sims, Physician and Man." Dr. Gibbes was introduced by Dr. Robert Wilson, dean of the medical college. The lecture was attended by the students, members of the faculty and other physicians of the community.

College of Medical Evangelists

Dr. Oswald S. Lowsley, New York, addressed the junior and senior classes at the College of Medical Evangelists, Los Angeles, February 12. On this occasion a moving picture on venereal diseases was shown. Dr. Emanuel Libman, New York, conducted a clinic for the junior and senior students, February 7, at which time two patients with Libman-Sachs' disease were presented.

Annual Nu Sigma Nu Lecture at Colorado

The third annual Nu Sigma Nu Lecture at the University of Colorado School of Medicine was given April 21 by Bradley M. Patten, Ph.D., head of the department of anatomy at the University of Michigan Medical School, Ann Harbor, on "Micro-Moving Pictures of the Early Development of the Cardiovascular System in Living Embryos." Dr. and Mrs. Patten and

several faculty members were dinner guests at the Nu Sigma Nu House before the lecture, and open house was held later in the evening.

Haggard Memorial Lecture at Vanderbilt

The Alpha Kappa Kappa fraternity at Vanderbilt University School of Medicine, Nashville, Tenn., has established an annual lectureship in memory of the late Dr. William D. Haggard, professor of surgery and clinical surgery at the school for many years before his death, Jan. 28, 1940. The first lecture was delivered on January 17 by Dr. Mont R. Reid, Christian R. Holmes professor of surgery at the University of Cincinnati College of Medicine, on "Experiences in Vascular Surgery."

"DO YOU KNOW"

Following are answers to the questions appearing on page 2550:

1. Alphonse Laveran (1845-1922) of Paris made this discovery, Nov. 6, 1880, while an army surgeon in Algeria. Dr. Laveran was awarded the Nobel prize in 1907.
2. Dr. Robert Seymour Bridges (1844-1930), the only physician to hold this position. Dr. Bridges studied at St. Bartholomew's Hospital, London, and held several hospital appointments in that city before withdrawing from the active practice of medicine at the age of 37. His last work, "The Testament of Beauty," was published in 1929.
3. Dr. John Brown (1810-1882) of Edinburgh, the pupil and later assistant of the famous Syme.
4. Sir James Mackenzie (1853-1925), a graduate of Edinburgh, first made simultaneous records of the arterial and venous pulses to elucidate the clinical condition of the heart. He practiced nearly thirty years in a small city, then went to London as consultant in 1907 and, according to Garrison, made his mark by his sincere, earnest attitude toward the sick and his sterling books on the pulse and heart disease, including angina pectoris. He retired from practice in 1918 and the next year started the Institute for Clinical Research at St. Andrews. Garrison considers Sir James one of the greatest modern bedside physicians; he attracted patients from all over the world. By a strange irony of fate, he died of angina pectoris, a disease of which at that time he probably knew more than any one else.
5. Leonardo Da Vinci (1452-1519), who was the first to describe hardening of the arteries. He originated the idea of studying anatomy for the purpose of improving art. His anatomic drawings made from actual dissections were so accurate that many of them could be used in textbooks of anatomy today. He was born in the village of Vinci, near Florence, Italy, and was placed in the studio at an early age, where he served many years as an apprentice of painting. His most famous portrait, Mona Lisa, was of the young wife of a rich old man, Francesco del Gioconda.
6. Fritz Schaudinn (1871-1906) in May 1905, while working with Erich Hoffmann. Schaudinn took his doctor's degree in zoology in Berlin in 1894 and in 1906 he became director of protozoology at the Institut für Schiffs- und Tropfenhygiene at Hamburg. He was the son of an East Prussian innkeeper.

UNTIL SEPTEMBER

The Student Section will not be published during June, July and August. In the meantime, papers, news and other items for the autumn issues of this section may be submitted.

Temperature: Its Measurement and Control in Science and Industry. Papers Presented at a Symposium Held in New York City, November 1939, Under the Auspices of the American Institute of Physics with the Cooperation of National Bureau of Standards, National Research Council and Officers and Committees of American Ceramic Society et al. Cloth. Price, \$11. Pp. 1,362, with illustrations. New York: Reinhold Publishing Corporation, 1941.

This is an authoritative, well documented, extensive survey of the whole field of temperature. Of the twelve hundred and ninety-two pages of text, some two hundred and fifty are directly concerned with temperature and its regulation in man and in industry with quite complete discussions of theoretical points, as well as practical applications and new methods and apparatus. There are thirteen chapters, each made up of from six to fourteen papers by recognized authorities in the field, as well as an extensive appendix and an excellent bibliography up to November 1939, and there are also frequently included discussions of the paper by other authorities. The section on temperature in biology discusses such questions as the temperature limits of life, the development of homeothermy in animals, temperature factors in production and the normal and febrile temperature pattern of laboratory animals. The section on temperature and its regulation in man considers among other things the temperature sense, heat exchanges under normal and abnormal conditions, standard operative temperatures and some of the earlier observations on reduced temperature therapy. The book as a whole is technical yet interesting reading. It should be an invaluable handbook for reference by any one interested in the subject of temperature, though the clinical implications and control of abnormal temperatures are not as fully dealt with as one might wish.

A Yankee Doctor in Paradise. By S. M. Lambert, M.D. Cloth. Price, \$3. Pp. 393, with portrait. Boston: Little, Brown & Company, 1941.

For twenty years Dr. S. M. Lambert was stationed in the South Seas working for the Rockefeller Foundation. To him particularly was assigned the control of hookworm. It became necessary that he determine the extent to which natives in all portions of the South Seas were infected with this parasite and also to apply the techniques that have been developed by scientists for the treatment of such infection. As a physician and sanitarian he did not limit himself exclusively to hookworm but became familiar with other conditions that are prevalent, including particularly leprosy, tropical sores and the venereal diseases. This book, however, is no dryas dust recapitulation of the epidemiology of the South Seas. It is more fascinating by far than any novels of the current season. It is devoted equally to the anthropology and to the ethnology of the native tribes. He relates with a sharp sense of humor innumerable incidents which add excitement to the life of a physician who serves among primitive peoples.

THE JOURNAL of Nov. 19, 1921 contained an article by Maurice C. Hall on the use of carbon tetrachloride in the removal of hookworm which was the answer to the problem of the control of hookworm, and the arrival of that issue in February 1922 in the South Sea Islands was the inspiration for the tremendous success which Dr. Lambert achieved in his work.

In this fascinating book is told the story of the 325 pound queen of Tonga. Here is revealed the development of pidgin English and the manner of its use in the promotion of modern health and hygiene. Here is the inside story of a health ambassador working with amazing success to preserve the lives of the Fijian race and attempting to bring to it the blessings of civilized man without the inevitable destruction that seems to be associated with the work of advancement of scientific medicine. Here is a book which might well be read by every medical student to prove to him that the inspiration and romance of medicine has not destroyed the inspiration and romance of medical service. No doubt, one of the most important of Dr. Lambert's

accomplishments was the establishing of a school for the teaching of natives, who will themselves endeavor to aid in the stamping out of the diseases which are destroying them. Today Dr. Lambert and his devoted wife have retired to a well earned rest in California, but for him and for every reader of his book Fiji becomes instantly alive and beckons.

Physikalisch-diätetische Therapie nach klinischen Gesichtspunkten. Von Dr. Hans-Georg Scholtz, dirigierender Arzt der Abteilung für physikalische Therapie am Städtischen Rudolf-Virchows-Krankenhaus, Berlin. Paper. Price, 15 marks. Pp. 303, with 93 illustrations. Leipzig: Georg Thieme, 1940.

This textbook is divided into two main sections. The first section deals with the technic of application, the physiologic effects of physical agents and the fundamentals and administration of therapeutic diets. In the second section the clinical application of physical and dietetic therapy is considered. The text is a peculiar hodgepodge of good and poor methods of treatment, hydrotherapy, colonic irrigation, thermotherapy, balneology, the use of various types of packs and compresses, light therapy, electrotherapy, including galvanic and faradic therapy and the employment of high frequency currents, mechanotherapy, including massage and manipulation, and the technic of local blood letting and Bier's passive hyperemia. In the part on dietetics, the author includes a discussion of the principles of nutrition, stipulations for the administration of therapeutic diets and indications for their employment in various diseases.

The text is well illustrated, but here again there seems to be little discrimination between what is good and what is bad in the field of physical and dietetic therapy. Whereas there are excellent illustrations on corrective exercises and under-water gymnastics, on the other hand there are many illustrations of antiquated devices such as the Schnee bath, queer and antiquated methods for applying colonic irrigations, electric baths and descriptions of such comparatively useless procedures as sand baths, all interspersed with excellent illustrations of the more modern methods of applying massage, heat, exercise and electrotherapy.

The part on dietetics seems to be subordinated to the section on physical therapy; it probably would have been best if this phase of the subject had been dealt with in a separate book. In the clinical section of the book the employment of physical agents and diets is considered in connection with the treatment of certain infections, circulatory, respiratory and rheumatic diseases, as well as in diseases of the gastrointestinal, genitourinary and nervous systems and disease of constitutional and metabolic origin. Although there is much of interest in this section, there is also the usual lack of discrimination concerning proper indications. The illustrations are numerous and good. There is an adequate subject index, but no bibliography or list of references is appended. The book is recommended to any one who is interested in this field of therapy and who is capable of discriminating between the suitable and unsuitable material presented in the text. It is not recommended for the beginner in this field of therapy.

Treatment in General Practice: Surgery (Continued). Volume IV. Articles Republished from the British Medical Journal. Cloth. Price, 16s. Pp. 562, with 143 illustrations. London: H. K. Lewis & Co., Ltd., 1940.

This volume is a satisfactory presentation of the treatment of many common surgical conditions encountered in peacetime practice, handled by the general practitioner. It is satisfactory because facts of practical importance are stressed in an authoritative way by adhering to well tested principles and, for the most part, to sound, accepted methods of treatment. None of the articles are long, controversial or concerned with obscure conditions. It is a tribute to the editing that there should be such uniformity in concise presentation of significant material on so many subjects by so many authors. Each chapter is introduced by sufficient description to make identification of the lesions possible, usually assisted by plain but adequate illustrations (although some of the photographic cuts are poor). This is important because not a few of the relatively common but disabling injuries with the treatment of which a general practitioner is frequently confronted (such, for example, as hand infections and injuries about the shoulder joint) are often not correctly diagnosed or properly treated.

The material covered includes common traumatic injuries of the extremities, chest and spine and their associated complications, frequently encountered disturbances of the genitourinary tract (urinary retention, phimosis, hydrocele), rectal lesions (hemorrhoids, prolapse, pruritus), common infections, simple amputations, the treatment of varicose veins and of the complications of varicose veins, and the prevention and treatment of bed sores and essential principles so far evolved in the use of the newer chemotherapeutic agents as applied to surgical disorders.

No effort has been made in any of the volumes of this series to deal specifically with the injuries of modern warfare. Much that the book says regarding trauma is applicable to the treatment of these conditions, but no special technics which apply to the handling of such injuries and no injuries peculiar to the present military situation are described. Any one interested primarily in the latter must look elsewhere, and for this reason the book may be undeservedly neglected. In spite of the unusual interest in military surgery at the moment, the book should be popular both in England and here: the points of view are essentially the same, the ground is well covered and the essence of each subject, because of the way it has been presented, is quickly and easily grasped.

A Method of Anatomy: Descriptive and Deductive. By J. C. Bolleau Grant, M.C., M.D., Ch.B., Professor of Anatomy in the University of Toronto. Second edition. Cloth. Price, \$6. Pp. 794, with 651 illustrations. Baltimore: William Wood & Company, 1940.

In the teaching of anatomy there is no substitute for actual dissection of the human body. However, anatomy books form an invaluable aid to the acquisition and retention of anatomic details. The various textbooks of anatomy have grown up traditionally with the development of the science of human anatomy and therefore represent careful analytic description and discussion revised again and again as they have been put to use and found wanting. The fact that anatomy is occupying less space in the student's curriculum necessitates a brief but thorough and more functional approach. That is the aim of this textbook. Its success can be appreciated only from experience. In many ways it should appeal to students who find existing textbooks replete with exhaustive and fatiguing detail. It resorts to simple uncolored drawings, usually schematic, which are easy to follow. It lacks the superb anatomic drawings of the better known anatomic works, and as a source of ready reference for review it cannot compare with the older style books. While it may prove of value in the teaching of anatomy, the student is less likely to treasure it and refer to it as he does the more exhaustive volumes. Students who use this book will be pleased by its refreshing attack on a difficult subject. Whether it can replace the well established, traditional textbooks is questionable.

Health of White Settlers in Surinam. By N. H. Swellengrebel, Professor of Parasitology, University of Amsterdam, Amsterdam, in collaboration with E. van der Kuyp, Government Physician Paramaribo. Colonial Institute at Amsterdam, Special Publication No. LIV. Department of Tropical Hygiene No. 16. Paper. Pp. 118, with 7 illustrations. Amsterdam: The Institute, 1940.

The International Refugee Colonization Society was founded in the Hague to finance the wholesale emigration of Jews and other refugees and to ascertain which countries would offer the best opportunities for settlement. From the first the organization was interested in Surinam in spite of its bad repute and the numerous failures at European colonization. Most of the work of the commission sent to Surinam was interrupted by the war, but the sanitary phases are preserved in this report.

The main portion of the report is divided into five sections as follows: general information, which includes a brief account of the climate, soil, population and governmental districts; sanitary conditions in Surinam, which summarizes and discusses the significance of the vital statistics of the area; sanitary history of the white settlement in Surinam; malaria in rural Surinam, and the prevention of diseases in a future settlement.

Professor Swellengrebel's scholarly and critical examination of the health conditions brings out some surprising conclusions. The health conditions on the coast of Surinam are

unbelievably good for a tropical area. They are exceptional in the tropical town of Paramaribo. In the rural areas malaria and hookworm lead all other diseases in importance, and the history of the attempts of white settlement in Surinam suggest that most failed because of malaria. In spite of these diseases, however, the average rural death rates are lower than in Paramaribo. The Bush Negroes are a serious reservoir of malignant tertian malaria for colonists, as they harbor large numbers of the parasite without marked inconvenience. In general, health conditions offer no obstacle to the settlement of Surinam with white persons provided the colonists avoid certain highly malarious areas (in particular the interior in or near the bush) and do not wantonly neglect certain elementary laws of health. Throughout his discussion the author, in common with certain other modern historians, warns against ascribing too great an importance to unfavorable health conditions as compared to economic factors in limiting colonization with white persons. The present volume is recommended as an exceptionally interesting and valuable contribution to tropical medicine.

Anatomy and Physiology Laboratory Guide. By Edmond J. Farris, Executive Director, Associate in Anatomy, The Wistar Institute of Anatomy and Biology, Philadelphia. Third edition. Paper. Price, \$1.60. Pp. 144, with 126 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1941.

While the reviewer is not familiar with earlier editions of this manual, it is obviously designed for a school of nursing. As such it appears to be admirably developed. According to the preface, some valuable improvements have been made. The general plan is one of integration of anatomy with physiology. For example, unit 1 is devoted to the body as an integrated whole, and in this is an introduction to anatomy together with some simpler physiologic experiments. Unit 2 deals with the erect and moving body and is similarly integrated. The illustrations include line diagrams, schematic diagrams, drawings and structures that the student must identify by labeling a roentgenogram of an erect human subject, colored schematic drawings of muscles, reproductions of simpler kymographic tracings and three full pages of photographs of laboratory equipment with sentence descriptions of each. There is also a table of more than forty teaching films, listed by unit, together with commercial distributors. This includes all the best sources of this type of teaching material. The manual contains a surprising amount of information for the purpose for which it is designed.

Diagnosis and Treatment of Arthritis and Allied Disorders. By H. M. Margolls, M.D., M.S., F.A.C.P., Chief, Arthritis Service, St. Margaret Memorial Hospital, Pittsburgh. Cloth. Price, \$7.50. Pp. 531, with 140 illustrations. New York & London: Paul B. Hoeber, Inc., 1941.

This book was written to indicate to the family physician the possibilities of preventing and treating arthritis and its allied disorders. The author emphasizes the purely clinical aspects of the treatment and simple office procedures. The introduction is well written. The illustrations of the constitutional basis on which atrophic arthritis is built, using the pyramid as an example, are instructive. The chapter on the pathologic changes is a little short. The author presents a fair and just account of the importance of focal infection in atrophic arthritis. In the illustration on head traction, the author has not shown the raising of the head of the bed. His discussions of the cervical rib and the scalenus anticus syndrome are well worth the time required to read them. One of the most valuable parts of the book is the author's fifteen section discussion of low back and sciatic pain. His choice of borrowed illustrations is good. The bibliography is up to date. On the whole this is a good book and is well worth reading.

Allgemeine Elektrokardiographie. Von Professor Dr. Eberhard Koch, Direktor des Physiologischen Universitäts-Institutes Gießen. Mit einem Anhang: Richtlinien für die Auswertung eines Ekg. Von Dr. Elisabeth Koch-Momm. Fifth edition. Paper. Price, 2.25 marks. Pp. 49, with 44 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1940.

The new edition is a slight amplification and revision of the previous edition of this short monograph. It is useful in introducing the reader to the theoretical aspects of electrocardiography. It can be recommended to those seeking such information.

QUERIES AND MINOR NOTES

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CLIMATE AND ARTHRITIS

To the Editor:—Would you please advise us regarding arthritis in North and South Dakota? We are interested in the prevalence in North and South Dakota, as well as whether a patient is benefited or harmed by residence in that state. We understand the ambiguity of the latter statement but would appreciate any information you may give us along these lines.

Percy A. Ward, M.D.,
John T. PETERS, M.D.,
Minneapolis.

ANSWER.—There are available no comprehensive figures on the incidence of rheumatic diseases in North or South Dakota. The recent (1935-1936) National Health Survey gave the national incidence of arthritis and rheumatism but not the incidence by states. Perhaps unpublished data thereon could be obtained from the United States Public Health Service, which conducted the survey. The incidence of rheumatic disease is reputedly considerably greater in the Northern than in the Southern states. For example, rheumatic fever is several times more common about latitude 47 north, that of North Dakota, than it is in latitude 25 north, that of Florida (Seegal, David; Seegal, Emily B. C., and Jost, Elizabeth L.: A Comparative Study of the Geographic Distribution of Rheumatic Fever, *Am. J. M. Sc.* 190:383 [Sept.] 1935. Nichol, E. F.: Geographic Distribution of Rheumatic Fever and Rheumatic Heart Disease in the United States, *J. Lab. & Clin. Med.* 21:588 [March] 1936). For the size of their populations there is probably more chronic arthritis in the Dakotas than in the Southern states. The inquirer, however, is obviously concerned not with the possible appearance of arthritis among nonarthritic persons who move to the Dakotas but with the probable influence of the climate on an already existing arthritis. It is not stated what kind of "arthritis" the patient has. Gouty and osteoarthritis (hypertrophic) are affected by weather less notably than is rheumatoid arthritis. Patients who have the latter disease generally feel worse in cold weather and in winter, better in warm weather and in summer; they often can predict the approach of a storm by an alteration in their symptoms. But there are so many exceptions to these generalizations that the effect of climate and weather on arthritic patients has never been precisely defined.

Climate and weather are a composite of temperature, humidity, barometric pressure, atmospheric electricity and other factors. Rentschler, Vanzant and Rowntree (*Arthritic Pain in Relation to Changes in Weather*, *THE JOURNAL*, June 15, 1929, p. 1995) noted that barometric pressure influenced the symptoms of most arthritic patients more consistently than did temperature or humidity. But it did not influence all arthritic patients in the same way; some felt better when the barometer rose, others felt better when the barometer fell. Humidity has a definite part in determining an arthritic patient's symptoms. The arthritic feel better on cold dry days than on cold damp days; also they feel better on hot dry days than on hot humid days; they may feel worse even than in winter time (Coste, F., and Forestier, J.: *Rheumatic Meteoropathology*, *M. Press* 97:116 [Aug. 10] 1938). And despite the notable shifts in temperature which occur between the winter days and the nights in Arizona, arthritic patients generally feel better there because of the stability of the other factors that may affect them adversely.

A recent survey led Tegner (*Treatment of the Rheumatic Cases in the United States and the Continent of Europe*, *Rheumat. Dis.* 1:249 [Oct.] 1939) to conclude that in the temperate zone local climate is a relatively unimportant factor in aggravating the symptoms of the disease, although it may be a more important factor in the tropics. Of greater importance than the general climate is "the microclimate" of the dwelling place (Hill, Leonard: *Rheumatism and Climate*, *Brit. M. J.* 2:276 [Aug. 5] 1939). According to Hill, damp, atmospheric electricity and cyclonic disturbances are important. Eskimos and Lapps have much less rheumatism in temperate zones who live indoors in badly insulated, artificially heated houses. Despite the cold, none of the arctic explorers had rheumatism.

The winters of the Dakotas are cold, but so are those of Minnesota, and it is probable that an arthritic person from Minneapolis would find no notable alteration in symptoms after moving to the Dakotas. Patients in these states would feel more comfortable were they able to avoid the rigors of the Northern winters. But to combat the latter much can be done in the way of warm, well ventilated houses, the use of warm but porous clothing, and the consistent daily use of various simple home methods of physical therapy supplemented by professional physical therapy and other remedies. Such is the nature of chronic rheumatoid arthritis that many a victim of that disease may be much better off in the Dakotas if he carries out a careful schedule of orthodox antiarthritic therapy than if he treks south to lie neglected in the sun without benefit of other treatments.

EFFECTS OF ORALLY ADMINISTERED ALUMINUM ACETATE SOLUTION

To the Editor:—Is aluminum in the form of liquor alumin acetatis ingested orally absorbed into the general circulation? Or is practically 100 per cent of it eliminated by the bowel? If absorbed does it affect the circulation, glands or other soft tissues or the bone? Is there any contraindication for its ingestion orally other than its slight astringent effect?

A. C. Howe, M.D., Brooklyn, New York.

ANSWER.—The soluble salts of aluminum, like those of other heavy metals precipitate proteins, are astringent and are only slightly absorbed if at all. Some of the early investigators reported that the soluble aluminum compounds are completely eliminated in the feces. Other investigators have shown that there is slow absorption of small quantities of aluminum compounds when taken orally. These small amounts are rapidly eliminated in the urine with no storage of aluminum in the tissues of the body. Symptoms of aluminum poisoning do not occur when aluminum salts are given by mouth, even in large doses and over long periods. The metal is excreted in the feces partly as phosphate, thus deflecting the phosphates from the urine or preventing their absorption and utilization. Unless the income of phosphorus is deficient, this is practically unimportant. Rickets has been produced in animals by continued overdosage with aluminum salts. Because they are not readily absorbed, even large doses cause only local exudative inflammation of the alimentary canal. The astringency of aluminum compounds tends to produce mild to severe constipation which may be controlled by the administration of liquid petrolatum.

Solution of aluminum acetate (Burow's solution) of the National Formulary VI contains about 5 per cent of neutral aluminum acetate and, as it is prepared from lead acetate and aluminum sulfate, it may contain a small amount of lead as an impurity. Solution of aluminum subacetate of the National Formulary VI contains about 8 per cent of aluminum subacetate (equivalent to about 10 per cent of aluminum acetate) and is identical to the solution of aluminum acetate (Burow's solution) described in the British Pharmaceutical Codex, except that the latter contains approximately 17.8 per cent of aluminum subacetate (equivalent to approximately 22.5 per cent of aluminum acetate). Neither of the National Formulary preparations is recognized for internal use, and the solution of aluminum subacetate of poisoning from the lead impurity. It should be noted that while the synonym Burow's solution is applied in both instances to the names solution of aluminum acetate and the British Pharmaceutical Codex, only the former containing lead as an impurity. The similarity of the latter with that of the official subacetate solution is illustrated as follows:

Solution of Aluminum Subacetate (N. F.)		Solution of Aluminum Acetate (B. P. C.)	
Aluminum sulfate.....	160 Gm.	Aluminum sulfate.....	225 Gm.
Acetic acid.....	160 cc.	Acetic acid.....	250 cc.
Precipitated calcium carbonate.....	70 Gm.	Calcium carbonate.....	100 Gm.
Water, a sufficient quantity to make.....	1,000 cc.	Distilled water.....	750 cc.

Recently A. J. Helfet (*A New Conception of Parathyroid Function and Its Clinical Application*, *Brit. J. Surg.* 27:651 [April] 1940) has reported the use of a solution of aluminum acetate in the treatment of parathyroid diseases. Based on the theory that retention of phosphate acts as a stimulus to increased secretion of parathyroid and that this results in a "compensatory" hyperparathyroidism with essentially normal glands and blood calcium and phosphorus values, this investigator has proposed the oral use of aluminum acetate for the removal of phosphate from the body in the treatment of secondary hyperparathyroidism.

QUERIES AND MINOR NOTES

Jour. A. M. A.
May 31, 1941

or generalized fibrocystic disease (not due to adenomatous parathyroid glands), rheumatoid arthritis and osteitis deformans (Paget's disease). The author indicates that decalcification of the skeleton (osteoporosis) and a negative calcium balance occur in these conditions and that this is suggestive of a hyperparathyroid state may be partially responsible for the latter conditions although no definite evidence exists to establish this point. In addition to a solution of aluminum acetate, 1 pint of milk is given daily as a source of calcium and vitamin D. The author gives a prescription which contains "Liq. aluminum acetate (B. P.)" 1 1/4 ounces with a sufficient quantity of the vehicle (used to disguise the astringency of the drug) to make 4 ounces. The prescription calls for a minimum dose of 1 drachm four times daily after meals. The British Pharmacopoeia describes no solution of aluminum acetate. It is therefore assumed that the author's prescription refers to the solution of aluminum acetate (Burrow's solution) of the British Pharmaceutical Codex. On this basis it may be computed that the amount of aluminum acetate in the proposed prescription is approximately 7.2 per cent. The author states that the prescribed amount of aluminum acetate has a phosphate combining power to from 150 to 220 mg. of calcium. Under the author's discussion of rheumatoid arthritis, however, the average dose of aluminum acetate is stated to be 1 drachm of a 2.5 per cent solution four times a day. Apparently a weaker solution was employed for the cases of rheumatoid arthritis than for fibrocystic disease and osteitis deformans. The 15 cases of arthritis treated showed no significant change in the blood calcium and phosphorus or in the radiologic evidence, although clinical improvement occurred in all but 2. Some increase in bone density was observed in 2 of the 8 cases of Paget's disease treated and in all 4 of the cases of generalized fibrocystic disease.

Besides being too inadequate to establish definite conclusions, the evidence presented by the author appears questionable when it is realized that the daily intake of milk of most of the patients treated with aluminum acetate provides more phosphorus than can be expected to be removed by combination with the amount of the drug given. The author indicates that an attempt to find an adequate diet of a constant low phosphorus content was abandoned as impracticable. As has been indicated, unless the phosphorus income is deficient, the removal of phosphates by aluminum acetate is of no practical importance. Further studies appear to be necessary before the usefulness of aluminum acetate in secondary hyperparathyroid states and rheumatoid arthritis can be established.

BENIGN TUMORS OF GALLBLADDER

To the Editor:—What is the prognosis of a small adenoma at about the ampulla within the gallbladder in a woman aged 34? The gallbladder fills and empties promptly. There has been vague distress at intervals for two years, and the roentgenogram suggests periduodenal adhesions. The appendix does not fill. The gastrointestinal tract is otherwise normal. There is never any jaundice. No change in size has taken place since the roentgen examination six months ago. The patient is in excellent health, and conservative treatment with roentgen rays once a year is considered unless statistics show the tendency to malignancy is too great.

D. G. Dudley, M.D., Endicott, N. Y.

ANSWER.—Benign tumors of the gallbladder, although apparently rare, have been sufficiently studied in surgical and necropsy specimens to indicate that two general types probably occur: 1. Those secondary to chronic proliferative cholecystitis. These are usually multiple. 2. Polyps and adenomas (adenomyoma, myoma, lipoma, myxoma and fibroma), usually occurring singly and regarded by Kerr and Lendrum (*Brit. J. Surg.* 23:615 [Jan.] 1936), in a review of the literature, as true tumors of the gallbladder in contradistinction to the first group.

The probability that such tumors may undergo malignant change seems to be small. Carcinoma of the gallbladder has been reported which appeared grossly like an adenoma (Lauritzen, S. H.: *Acta chir. Scandinav.* 79:105, 1936. Eiserth, P.: *Virchows Arch f. path. Anat.* 302:717, 1938). Presumably these tumors were not malignant from the onset. Eiserth found 13 adenomas, one of which showed microscopic evidence of malignancy, in approximately 4,000 gallbladders. These reports are chiefly concerned with stressing the possibility of malignant degeneration. On the basis of surgical and necropsy material it would appear that carcinoma may arise in papillomas or polyps of the gallbladder but that this has been observed in only a small proportion of the cases.

There is little, if any, evidence that polyps seen by cholecystography have undergone malignant change. Whether this indicates that polyps of gallbladders which concentrate dye sufficiently to visualize differ in their potentialities from clinically unrecognizable polyps is not known. It should be emphasized that an insufficient number of cases have been studied by cholecystography and eventually followed to operation or necropsy to justify statistical conclusions.

In view of these considerations and the fact that the diagnosis of polyp of the gallbladder by a competent roentgenologist has at times not been confirmed at operation or necropsy, medical management would seem to be the treatment of choice. Indications which would justify operation are (1) symptoms definitely referable to the biliary tract which fail to respond to medical treatment or (2) an increase in the size of the filling defect in the gallbladder (Walters, Waltman, and Snell, A. M.: *Diseases of the Gall Bladder and Bile Ducts*, Philadelphia, W. B. Saunders Company, 1940, p. 471).

ERUPTION OF TEETH

To the Editor:—A boy at the age of 4 fell and knocked out two teeth, the upper central and lateral incisors. A roentgenogram taken about a month later showed the permanent teeth well formed. This was four years ago, and these permanent teeth have not erupted. Several roentgenograms in the past year have shown the teeth well formed, and the dentist has been expecting them to grow out of the gum at any time for the past year. He is now a healthy, well developed boy of 8. He is about 2 inches taller than the average, and his weight is about average for his age. He was a bottle fed baby. He has had no serious illness except bronchopneumonia two years ago. His baby teeth were slow in developing. He has shed his remaining upper and lower incisors, and the permanent teeth have grown in normally. Any suggestions you can give to stimulate the growth of these teeth will be appreciated.

W. J. Graber, M.D., Beaumont, Texas.

ANSWER.—The eruption of the teeth appears to be related to periodontal vascularity. Vigorous rubbing, therefore, of the gingival tissue which overlies the unerupted teeth with the fingers and a tooth brush is likely to facilitate their eruption. If this procedure is not effective, it is possible that eruption has been delayed because of a mechanical obstruction of the overlying soft or even osseous structure, which normally should atrophy or become resorbed. The surgical removal of the overlying gum tissue or bone and the exposure of the incisal portions of the teeth are then indicated.

SENSITIVITY TO FACE POWDER AND PERFUME

To the Editor:—A patient is sensitive to orris root. She has a vasomotor rhinitis but will not use any hypoallergic powder. She buys expensive powder from the department stores, and they assure her that the powder is free from orris root, lead and rice. A cutaneous test with her new powder is positive but not so strong as with orris root. Are there any chemicals related to orris root in the ordinary powders which will sustain the symptoms? She is receiving injections. Will it be necessary for her to use only hypoallergic powder?

Elk Tannenbaum, M.D., New York.

ANSWER.—The only possible allergenic substance which may be included in powders and which may sustain the allergic symptoms, in the absence of orris root and rice starch, is wheat starch. Few cosmetic manufacturers use any starch in their powders, and orris root is rarely used. The probabilities are that the patient may be sensitive to the perfume used, since the vast majority of persons sensitive to face powders are also allergic to the essential oils. Of course in rare instances some people may be sensitive to the individual components of a cosmetic which would ordinarily be considered nonallergenic.

MUSHROOMS AND HYPERTENSION

To the Editor:—Can you advise me concerning the use of mushrooms in the treatment of high blood pressure? I know they long have been of some use, but I'd like to know what references there are on studies in the use of this succulent food. I know parsley and garlic are used as well.

John Fassett Edwards, M.D., Easton, Pa.

ANSWER.—There is no scientifically valid evidence that mushrooms have any therapeutic value in hypertensive arterial disease.

REDUCED SPERMATOZOAL FERTILITY

To the Editor:—May I take exception to the answer to the question headed "Few Motile Spermatozoa After Operation for Cryptorchism" in *Queries and Minor Notes* (April 12, 1941)? This stated that "at present there is no satisfactory method of inducing spermatogenesis." The man in question has a basal metabolic rate of minus 11, and a few motile spermatozoa were found in his specimen of spermatic fluid. The urologists of our sterility study group have been classifying in the relatively sterile, rather than absolutely sterile, group all men whose specimens show any spermatozoa at all, alive or dead. The reason for this is that some of these persons may be improved by proper treatment to fertility levels. The treatment consists of limited courses of stimulation by gentle prostatic massage, anterior pituitary-like sex hormone and obviously in this case thyroid substance, the latter over more prolonged periods. Vitamin E would seem also to be indicated. Our experience has been that the outlook for such a patient is by no means hopeless as far as spermatogenesis and children are concerned.

Paul Titus, M.D., Pittsburgh.

CURRENT PROBLEMS OF AMERICAN MEDICINE

PRESIDENT'S ADDRESS

FRANK H. LAHEY, M.D.

BOSTON

Probably few presidents of the American Medical Association have been or will be inducted into the office in more uncertain or more urgent times. It is important, therefore, to inquire as to whether or not the American Medical Association has been fulfilling its obligations in these times. As I observe its activities and the results of these activities, it seems to me beyond any question that this query can be answered in the affirmative. At the very outset of these turbulent times the American Medical Association offered its services to the national government in the way of ascertaining the availability of doctors for service, and this offer was promptly accepted by the government. Facilities were promptly set up at the headquarters in Chicago to send out the necessary questionnaires; the necessary financial means, the office help and the mechanical facilities to handle the details of the questionnaires were provided, and the undertaking was immediately begun. Questionnaires were sent out to the latest known address of 186,303, and more than 150,000 have now been returned. Of this group about 146,000 have now been tabulated and put under the punch card system, so that they are available for immediate use for government needs. In addition to this, report forms have been sent through state medical society headquarters to all county medical societies to ascertain the availability of physicians for the care of those who are occupied in industry in the United States. These details are familiar to every one, but a nonboastful consciousness of a piece of work well done is the right of every individual or group. It would not be immodestly self approving for us as representatives of the American Medical Association to say that the undertaking of providing physicians for the care of our army, navy and industry would have been a much more difficult one, one requiring a much greater amount of time and one that would have been much less efficiently done were not the facilities, resources and records of the American Medical Association available and utilizable.

This is merely a single small example of the often unrecognized and unappreciated advantages resulting to this country from medicine having so efficiently organized itself.

President's address before the American Medical Association at the Ninety-Second Annual Session, Cleveland, June 3, 1941.

PROVISION OF MEDICAL PERSONNEL

As the result of their experiences in the last war, doctors have been apprehensive lest the mistakes made in that war as relates to the Medical Corps would be repeated in this war. No one believes that it is possible in an undertaking of such magnitude as is the raising and training of such a large army and navy as we must have that mistakes will not be made in the Medical Corps and that some of the mistakes even of the last war will not be repeated. We all expect that this will be so and likewise we all expect to be tolerant concerning these mistakes, in view of the size of the undertaking. It is fair, however, to request that the major mistakes of the last war are not grossly repeated, that the value so far as possible of assigning men in the service to work with which they are familiar and for which they are trained is appreciated. It is but fair to ask likewise that the need for the continuing production of well trained doctors be not overlooked. For a period it seemed possible that this mistake might be made, but it now seems probable that those in whose hands the destiny of the country rests are becoming increasingly aware of the dangers of in any way interfering with the constant production of doctors. Not only would it be a short sighted policy to interrupt their education while in the medical school, but within reason it would be likewise short sighted to deny them at least some period of practical hospital training. Obviously it will not be possible in the present situation to provide as ideal a period of hospital training after graduation of medical students as can be obtained in less troubled times, and to meet these times a compromise between what is ideally desirable and what is practically feasible represents the need of the situation.

DEFERMENT OF MEDICAL STUDENTS

We can well take a page from England's book regarding doctors and realize that not only are medical students not permitted to be drafted but they are not permitted to volunteer. The yearly production of doctors in this country amounts to about 5,000. Of the doctors practicing in this country about 3,800 for various reasons such as old age, sickness and death become unavailable for service, and the yearly demand for doctors in the various branches of the service amounts to about 3,500. No one has any idea how long it will be necessary to maintain such an army and navy as is contemplated, and it is therefore evident that the simple dictates of good sense indicate the necessity of the constant production of a supply of doctors. We should insist, therefore, not only that those who are in the course of their medical education should be maintained in it but also that those who are

definitely committed to the study of medicine and are in the premedical preparation period should be permitted to continue.

SELECTIVE SERVICE ACT

As a member of an appeal board which has now been functioning for several months, I have had the opportunity to be in close personal contact with the quality of the functioning of the Selective Service Act. As a result of this experience it is my opinion that it is being handled well, being honorably conducted, that men are being selected on a fair and just basis and that politics is having, at least as far as I have observed, practically no influence on the character of its activity. There are a few features concerning the Selective Service Act which need clarifying, however, in order that it may function more justly to all and be less dependent on individual interpretations of the act. These are particularly a greater stressing of the need of exempting trained mechanics and a more standardized policy as to the induction of married men. It is easy for a drafting board to assume that any one asking for exemption is seeking to avoid duty, with the result that men are being lost to war work who are urgently needed. These defects doubtless with further experience will be so clarified that this desirable end will be brought about.

It seems probable that as time goes on there will be greater and greater need for more help from the medical profession. There has been no group of men in periods such as these who have been more willing to serve than have the doctors. I feel sure that the demands to be made on us, which unavoidably and certainly must come in the ensuing months, will be met with satisfaction to our government and with credit to our profession.

A position also worked out by the English is worthy of our consideration and undoubtedly will eventually have at least to be thought of as a possibility—the development of a quota system as relates to the selection of American doctors. There has already been a greater number of medical volunteers from the South than from the North, and there will probably be areas where, as a result of greater volunteering, the number of doctors available for the community will be too limited. Should the present situation become even more urgent than it is, it is conceivable that many hardships may be worked in communities. An ideal arrangement in England has been worked out by means of the so-called quota system, by which committees select the number of men who are to go from different areas and suggest individuals for selection. These individuals are permitted as are draftees to make appeal, submitting their reasons, which are given serious consideration before the matter is settled. Obviously, the criticism of this is the question of its feasibility in a democracy such as ours. It may well, however, eventually prove necessary and should be in our minds at least as a possibility.

MEDICAL EDUCATION

I have always been interested in medical education, having spent a considerable portion of the first part of my life in undergraduate education and a definite portion of the latter part of my life in postgraduate education. Having been literally steeped in clinical medicine and surgery, I have at least a background of experience from which to develop some convictions regarding the subject.

It has always seemed to me that one of the greatest difficulties in medical education was to maintain a proper balance between the scientific side of medicine

and the practical side of medicine, the research aspect of medicine and the clinical aspect of medicine. It has always seemed to me important for every doctor to keep constantly before his mind the remembrance that the practical purpose of medicine is to care for the sick. As I have observed medical education particularly as it relates to surgery, since this is the field in which I am best qualified to judge, it has seemed to me that clinical surgeons are too apt to overvalue their clinical experience and technical skill and so unjustly depreciate professors of surgery doing a limited amount of actual surgery and a considerable amount of surgical teaching and experimental investigation. This can be and at times has been a real injustice. There are many teachers of surgery combining clinical and technical skill, investigative interest and . . . train and produce excellent young surgeons. There is, however, a certain amount of justice at times in this criticism, owing to the fact that medical schools often tend to place too many executive burdens on the heads of their department of surgery, to evaluate the quality of their professors of surgery too much in terms of their research products and to desire that their professors of surgery be excellent clinical surgeons but still turn over a large part of the clinical surgery to be done by residents in order to turn out the largest possible number of trained and experienced surgeons. As one who has spent his life busily occupied with clinical surgical problems and a large amount of actual personal operating, I am convinced that to teach surgery one must be busily occupied with the actual problems of surgery, that to be able to stimulate an interest and curiosity in surgery the teacher of surgery must be able to discuss the subject with his students not in terms solely of literature, theory or laboratory, although this is essential, but in terms of actual large personal experience. It has always seemed to me futile to assume the position that surgeons can be made by any other way than by surgery. With justice to both sides of the question, those who are daily occupied with the practical and technical sides of surgery must be careful lest their criticism of research surgeons does not constitute an apology for the lack of this quality in themselves. So, too, those who are busily occupied with undergraduate teaching and laboratory investigation must realize that their constant contact with relatively immature medical minds and their occupancy of an almost revered position in these as yet inexperienced minds does not cause them to acquire the habit of talking and thinking from above downward. If we could all remind ourselves several times each day that none of us in any branch of medicine are as great or as important as we think we are, and more important still than that, never as great as others sometimes think we are, it would be a fine thing.

ELEVATION OF MEDICAL STANDARDS

I am daily impressed with the fact that the standard of medicine is being constantly and satisfactorily elevated and I am more and more impressed with the fact that the best way to elevate medicine is to teach the people what good medicine is, on the one hand, and, on the other, to strive, as is constantly being done by the profession, to elevate medicine within itself. This will, in my opinion, accomplish more with less dislocation of what has already been accomplished in medicine than any other plan. While it is a little discouraging to see quacks flourishing and nostrum manufacturers prospering, one must remember that that has always been the privilege of the people through

generations. I have little faith that gullibility will ever completely cease to be a human failing. I have a definite conviction, however, that with legislative acts as to truthful advertising, that with the pure food and drug laws, that with the greater interest on the part of the public in reading sound articles on medicine and with greater effort on the part of medicine, in which the American Medical Association has played no small part, to raise the standards of medical education and the quality of hospital service, the standards of medicine in this country are being soundly and progressively elevated to a level which is not only gratifying to us but a credit to our country in the eyes of the world.

The activity of qualifying boards over the past and recent years promises with time to do something which has been urgently needed for a great many years, that is at least to exercise a quality, and possibly also in the course of time a quantity, control over specialization.

THE NURSING SITUATION

As I have observed the changes in medicine from time to time, I have been increasingly apprehensive concerning the nursing situation. I am highly conscious of the fact that criticisms of some of the present trends in nursing may meet with far from approving reactions on the part of the nursing profession. Since I speak as one in daily contact with the nursing problem at the bedside, in an executive capacity and in its specialized branches, I am at least qualified by experience to make some observations concerning it. I have been fearful for a number of years that the trend in nursing is away from service to the patient and too much in the direction of higher education. I have been fearful lest the higher and higher standards of requirements for entrance and graduation in nursing might not make it more and more difficult to obtain a sufficient number of nurses to meet our increasing demands. This is an apprehension which our present situation as relates to nurse shortage indicates as being more and more justifiable. What with the demands made on nursing at the present by army service, by public health, by industry and by other special branches in nursing, together with the relatively high cost of nursing for patients, it is necessary for nurses, physicians and legislators to have in mind at least the possibility of the employment of the practically trained nurse to meet the financial demands of the situation and the lack of personnel in the way of trained and registered nurses. It would be wrong for me with my interest in nurses and their future not to suggest to them that they take heed lest they educate and legislate themselves out of the important place they have held in medicine and in the community. It is really no exaggeration to say that, with many of the personal attentions to patients delegated to ward maids, the real art of nursing can be lost to the nursing profession.

ANESTHESIA

Having spent my life as I have in surgery, it is but natural that my observations should relate themselves to problems intimately connected with this branch of medicine, among which stands out most importantly that of anesthesia. I have been interested in the subject of anesthesia for a great many years. I have been interested in the training of anesthetists, I have been interested in elevating the standards of anesthesia, and I have had definite convictions that, by the training of good anesthetists and the elevation of the standards of anesthesia, operative procedures could be made more safe for patients, that fewer complications under

some of the newer forms of anesthesia would result and that operative procedures could be made infinitely more comfortable for patients under some of these newer forms of anesthesia. A greater and greater experience with these methods and the development of a larger and larger department of anesthesia in the clinic have convinced me more than ever of the soundness of these convictions. I have for a number of years mildly and gently reproached medical schools for their lack of interest in teaching and furthering the development of anesthesia. It has not been an easy task to accomplish the progress which, with the aid of a few enthusiastic pioneer anesthetists, has been obtained in this field, and there is still a large opportunity for greater progress in this department of medicine. There can be no doubt in the mind of any one who has had sufficient experience with the newer developments in anesthesia in the hands of those expert to employ them that they have made possible operative procedures hitherto deemed unfeasible, that they have lowered mortality rates and lowered morbidity. There is no doubt in my mind, as I wrote in a recent editorial on this subject, that the hospital which does not have anesthetists trained and experienced in all of the newer developments of anesthesia—endotracheal, ethylene, cyclopropane, regional, field block, pontocaine, nupercaine, continuous spinal anesthesia, intravenous pentothal, cervical block, paravertebral block and suction bronchoscopy—will not be in step with the times, that a hospital not having these facilities will not be able to show the low morbidity and mortality rates that a hospital possessing these facilities will be able to show. I am impressed with the fact that the frequent explanation of why such anesthetists are not employed in hospitals is that hospitals cannot afford them. It is my distinct conviction in many instances that this is due to the fact that many hospitals employ nurse anesthetists at relatively low salaries with a profit to the hospital. No reflection on nurse anesthetists is intended. Under the direction of trained physician anesthetists they can have a real place in the administration of inhalation anesthetics. To be sure, this profit is usually employed unselfishly in doing further charity work, and yet this is not rendering to the patient the best possible service for which he pays. While these remarks may seem a little critical, I am pleased to say that as I travel the country I see an ever increasing interest in this subject and an increasing number of hospitals which employ trained anesthetists and the advances in anesthesia.

POSTGRADUATE EDUCATION

One of the facts which has always impressed me about American medicine has been the thirst for knowledge on the part of physicians. As I travel the country from one end to the other, I am moved by the number of doctors who are willing to give up their practice, to travel limitless numbers of miles to acquire knowledge. As I see them in postgraduate meetings, often the same faces in the front rows, taking notes, listening attentively hour after hour, I am deeply impressed with the sincerity of their purpose, with the height of their ambition to improve themselves and with the zeal they display in accomplishing this. I doubt if there exists a group of men in the world who labor more diligently or more religiously or with greater constancy to improve their knowledge than do doctors. One has but to tabulate the number of postgraduate teaching courses going on in this country, the number of organized medical society meetings before which papers are read and the number of doctors who are in constant motion

in the way of visiting medical centers, medical schools and clinics to be convinced of the truth of this statement. The popularity of postgraduate teaching meetings is evidence of the fact that knowledge is being sought and these meetings are answering a real need.

There is an aspect, however, of this situation which needs consideration, and that is from the point of view of the talent available for this postgraduate teaching. Should the number of postgraduate seminars increase materially, it will be necessary either for these seminars to develop additional teaching talent or for some of the teachers at these seminars to arrange to eliminate their practice at home and to accept the fact that they are to become full time postgraduate teachers. It has always seemed possible to me as one busily occupied in postgraduate teaching that a better control in the way of spacing and planning postgraduate seminars could make them even more valuable to those physicians who wish to attend them and less burdensome to those teachers who are in the habit of occupying positions on their teaching staff. This suggestion is presented not as a personal complaint but as a suggestion whereby the quality of postgraduate teaching could be maintained and perhaps even improved.

WAR BETWEEN CAPITAL AND LABOR

It is impossible it seems to me in these times, and for any man with convictions, to make a presidential address without discussing in some degree world affairs. In the beginning of this address I stated that probably no President had been inducted into office in the American Medical Association in more uncertain or more urgent times. It is of interest perhaps in discussing our present situation in general terms to inquire why they are uncertain. They are unavoidably uncertain I believe as far as we are concerned because of world conditions. They are uncertain because we enter these conditions after a period of financial depression, after a period of economic experimentation which has been by no means successful in accomplishment, and this is said without criticism. No experiment can be certain of successful outcome before it is tried. They are uncertain because we have witnessed, perhaps unavoidably, a division of the country into bitter and hostile camps, both of which have been guilty of shameful exaggerations and untruths, if not premeditated misstatements about each other. Uncertain because labor and capital also are so irrevocably at odds with each other. Admitting the undeniable short-sightedness of capital while in the saddle, and no one who is honest can doubt it, there is little evidence that with labor in the saddle, as it is now, it is making any better job of it. Tolerance, forbearance, charity and moderation are apparently qualities not associated with those to whom is given the direction of large affairs. It appears equally lacking in capital and in labor, and one must have in mind the effect of such large authority and power on the minds of men as to their ability to think clearly, to project their minds clearly into the future in terms of possible distant effects, and to deal with situations justly and wisely without fear and without selfish interest.

SOCIAL GAINS AND PRESERVATION OF DEMOCRACY

What do we need in this present turbulent, uncertain situation more than anything else? Preeminently an understanding of the seriousness of the situation. There is nothing, it seems to me, more necessary and more lacking in the present situation than an appreciation of its seriousness. It is likewise apparently a human attribute to fail to face disagreeable facts—to make

them easier to live with by depreciating them or by not admitting their existence—and yet this has been one of the most expensive attributes to races and countries of recent times. In view of what I have for months insisted on, the real urgency of this situation is that we need outstandingly a dispersing of internal conflicts until the question of what is going to happen to the country is settled. Of what value is it to either side to win a victory in internal conflicts with the future of the country really uncertain, as I again insist it is? We should all make some generous gestures, and the higher places from which they are made the better will be the example and the better it will be followed. Let us all accept the taxes without question, let us support without complaint any increases that are necessary, let those of us who opposed the present administration accept and support it wholeheartedly and during this emergency withhold criticism of it except when we have constructive suggestions to make.

An immediate constructive suggestion, it seems to me, is real evidence that an effort is being made to reduce general expenses, not so that you and I can have less taxes but so that more money can be made available for defense expenditures. We ask for better evidences that reforms are to be set aside if only temporarily until the present emergency is over, better evidence that personalities with divergent opinions demonstrate better tolerance of their opposing points of view. We should all have a conviction concerning the war, but the nation should take a position very soon and, regardless of what we have said or thought, there must be national unanimity. If we are still in the stage of debate, let it be fair, free, unrestricted and without penalty. We must and at no late date, however, establish what is to be the policy of this nation as relates to the war situation. To my mind there is nothing and in the history of this country never has been anything which will influence the future of America more than the nature of this decision. When it is made, one of the most futile, stupid and unpatriotic things one could do would be to attempt to change that decision. Whether it is to be war or so-called all out support short of war, it is important to realize now before this decision is decisively made that there will then be only one kind of Americanism, that is the kind with 100 per cent support.

My own opinion, and I believe that it is my duty to express it, is that we are already committed to a position, whether we like it or not. I myself like it. We have dared the dictator. It is too late to appease him, and the word has no meaning in his language. We should arrive at a conviction concerning isolation. Is it right? It is my conviction that it is not. I prefer destruction if it need be to survival in covering terror. Give me positive commitment rather than compromising, unsatisfying safety. If I must face my friends in democracy trying to explain my reasons for seeking dubious safety and leaving them to their fate, I prefer the uncertainties of the hazardous undertaking frankly faced as hazardous, and to accept them. It is my opinion that if disaster should overtake us in this hazardous undertaking it would be no more terrible than what will happen to us if we are to try to isolate ourselves. We shall still have ourselves to live with. This nation has been gallant in the past and it can be gallant again. I do not believe that there is a safe course. In dangerous times such as these I would like to make as a closing statement that it is my conviction that a dangerous course has real advantages.

THE FATE OF PATIENTS WITH
UNTREATED BRONCHIECTASIS

HOWARD H. BRADSHAW, M.D.

FLOYD J. PUTNEY, M.D.

AND

LOUIS H. CLERF, M.D.

PHILADELPHIA

It is commonly assumed, in the absence of any real proof, that patients with a chronic productive cough and sputum that is free from tubercle bacilli are not seriously ill. Such patients are considered as having "chronic bronchitis," and often no real attempt is made to do much for them either diagnostically or in instituting therapeutic measures. These patients may be able to carry on routine activities throughout a greater part of the year but frequently are incapacitated for a longer or shorter period each winter. They have many episodes of acute infections of the respiratory tract usually diagnosed as pneumonia, pneumonitis or pleurisy. It usually is the acute phase of the disease that has concerned the physician. It is our purpose in this paper to present a follow-up study on 242 cases of bronchiectasis.

With the increasing use of surgical measures in the treatment of bronchiectasis, it is important to evaluate carefully the life expectancy of patients not receiving treatment. One may properly ask Is it justifiable to urge an operation of the magnitude of pulmonary lobectomy or lobectomies? What is the outlook of patients with bronchiectasis if surgical intervention is not instituted? Information concerning these questions should be available to the physician who treats patients with bronchiectasis. The mortality from the operation has been lowered to reasonable figures in skilled hands, approximately 10 per cent. For unilobar disease the mortality is under 5 per cent. Few reports bearing on the mortality from the disease itself and from its complications are available. The frequent fatal termination of bronchiectasis apparently is not well understood.

The cases of bronchiectasis included in this report have been diagnosed by roentgen ray studies and the employment of iodized oil or by bronchoscopy. The latter method of diagnosis may be open to some question. With a bronchoscope one can determine the condition of the bronchial mucosa and bronchial spurs and the presence or absence of pus—in other words, pulmonary suppuration. One may not be able to ascertain the exact cause of the suppuration; however, in expert hands the diagnosis by bronchoscopy can be relied on to a great extent. Iodized oil was first used for lung mapping in the Jefferson Medical College Hospital during 1925, and therefore this report includes cases diagnosed as bronchiectasis between 1925 and 1935, inclusive. The year 1935 was arbitrarily chosen because it was thought that after that date adequate time had not elapsed for accurate data to be available. Most reports on bronchiectasis include data up to the time of writing. It does not seem logical to include in a prognostic study of chronic disease cases that have only recently been diagnosed. No cases are included in which a foreign body was the etiologic agent. Bronchiectasis resulting from a previous pulmonary abscess or from tuberculosis also is excluded. Only those cases of bronchiectasis which presented no known etiologic agent are included.

A study of this character is of necessity incomplete because of the difficulty in making contact with patients

or their relatives. Many of them come from great distances. The method used was to send a comprehensive questionnaire to each patient. If no reply was obtained, a letter was sent to the referring physician, and if no information was obtained from these sources, the Retail Credit Company was employed to trace the patient. If evidence was found that the patient had died, the Bureau of Vital Statistics was asked to send a copy of the death certificate. Admittedly there are many inaccuracies, but in a general way the facts obtained are probably representative.

As previously stated, few reports are available on the fate of the patient with untreated bronchiectasis. There are many reasons for this. Few hospitals or clinic groups have an opportunity to see many patients with this disease. If there are no facilities to carry out appropriate studies or treatment the illness of many of these patients will not be diagnosed accurately. Bronchographic examination as a diagnostic aid has been employed only fifteen years. In many clinics its use is more recent. It commonly is not employed as a routine in diagnosis unless surgical treatment is contemplated. Frequent use of bronchoscopy as a diagnostic aid has been confined to a few medical centers until recently, and its routine employment in the study of cases of chronic cough still is not extensive.

A brief review of the literature on the prognosis of bronchiectasis reveals a wide variation of opinions. Jex-Blake¹ found bronchial obstruction present in 37 of his series of 105 patients coming to autopsy. Bronchopneumonia accounted for 31 per cent of deaths. He expressed the belief that the disease was probably rapidly fatal. Boyd² studied 56 cases during a ten year period; all the patients were children, and in most of them the onset occurred before the age of 2 years. Of these, 7 died, 4 of bronchopneumonia, 2 of miliary tuberculosis and 1 of nephrosis. Roles and Todd³ had 106 patients with bronchiectasis proved by iodized oil and followed from three to six years. The total mortality regardless of type of treatment or with no treatment was 38 per cent. The mortality in medically treated patients was approximately 50 per cent, and among surgically treated patients it was approximately 30 per cent. Lebert⁴ performed autopsies on 52 patients with bronchiectasis with the following notation: Twenty-one per cent had lived one year from the onset of symptoms, 7.7 per cent had lived two years, 30.7 per cent had lived three to five years, 15.5 per cent had lived six to ten years and 25 per cent had lived ten years from onset of symptoms.

In Warner's⁵ series the average duration of the disease from the onset of symptoms was ten years.

of life from inception of the disease to be two and sixty-three hundredths years. Raia⁷ studied 33 children with bronchiectasis who had been admitted to the hospital between 1932 and 1938. Iodized oil was used in 30; the remaining 3 were too ill to have the injection given, and all 3 died. Raia expressed the belief that unless infection is controlled all types progress to the more severe, sacular form. He had 11 patients with this type: 4 patients remained unimproved, 2 died from the complications of bronchiectasis, 4 had a rapid downhill course necessitating surgical intervention and 1 had a thoracotomy for drainage.

In 1939 Selby⁸ reviewed 120 cases of bronchiectasis in children in New South Wales. He traced 56 of 120 patients who had been admitted between the years 1918 and 1938. He included data on children who had not had studies done with iodized oil. It is impossible to arrive at any mortality figure from Selby's study because, of the 120 patients, 35 were living and were interrogated, 21 were dead and 64 were untraced. Since the Registrar General had no record of death among the 64 untraced patients, Selby expressed the belief that probably none of them had died. However, it does not seem accurate to include untraced patients in any follow-up study.

The largest series of cases of bronchiectasis in the literature was that of Perry and King.⁹ Their report

was based on 400 cases diagnosed by roentgenographic examination; the 400 patients were admitted to the Massachusetts General Hospital between the years 1926 and 1938, inclusive. One hundred and forty of these patients had undergone major surgical operations and were eliminated from this study. Of the 260 patients who did not have major operations 144, or 55 per cent, were known to be living in January 1939, 66, or 26 per cent, were known to be dead and 49, or 19 per cent, were not traced. If the untraced group is excluded, as it seems more accurate to do, then the mortality rate can be based on the traced patients alone. Of this group of 211 patients 66 are known to be dead, giving a mortality rate of 31 per cent.

Of the 144 living and traced patients, 127 continued to cough and 123 raised sputum; 33 had hemoptysis. Thirty-eight per cent were in excellent condition, 42 per cent in fair condition, 15 per cent in poor condition and 5 per cent in extremely poor condition. Forty-one per cent of those dead had died within five years of the onset of symptoms. (It should be remembered that this series includes cases diagnosed up to a period within a few months of writing.) Seventy-eight per cent of the dead died directly as a result of their disease. Only 6 of 114 patients who were checked after the

disease had been present from one to nineteen years showed any evidence of spread, and that was doubtful. Once bronchiectasis has been well established and proved by studies with iodized oil, does the bronchial system ever return to normal? This question has not been entirely settled, but many authors have reported the disappearance of symptoms and roentgenographic

evidence of bronchiectasis. Duken and von den Steinen¹⁰ stated that in young children the lung has the ability to repair itself and the growth factor compensates for the destructive process by the development of new, healthy tissues. Erb,¹¹ in discussing the pathology of bronchiectasis, stated that the appearance of the bronchi in the early stages, before relining with epithelium takes place, is such as to suggest that healing at this stage with actual diminution in size may be promoted by bronchoscopic drainage. When once the bronchi become relined with epithelium, such healing is no longer possible.

After one has had the opportunity of examining many surgical or postmortem specimens taken from patients with bronchiectasis, one is at once impressed with the degree of dilatation of the bronchial lumens and the thickness of the bronchial walls along with advanced fibrosis of the intervening pulmonary parenchyma. That such extensive change ever returns to normal seems unlikely. It seems probable that in young children with early minimal involvement proper bronchial drainage may restore the lung to normal in a certain number of cases. We have seen patients who had demonstrable bronchiectasis at one time but in whom at the present time symptoms are lacking and studies with iodized oil give negative results; this, however, is unusual. Cookson and Mason¹² stated that there appeared to be no reliable statistics dealing with the expectation of life in cases of bronchiectasis in which conservative measures have been solely relied on.

Table 1 shows the grouping of the 242 patients studied. After the elimination of all the cases of bronchiectasis which may have been due to a pulmonic abscess or to the prolonged sojourn of a foreign body in a bronchus, those presented here represent as nearly as possible only cases of bronchiectasis with no positively identified etiologic agent. The etiologic factors tabulated represent merely the condition from the onset of which the patient dated his symptoms of bronchiectasis. Whether any of these conditions should be seriously considered as causative factors is debatable.

For the purpose of this study only data on the living patients who have not had regular bronchoscopic treatments and those not subjected to major surgical intervention are included along with the data on patients who have died from bronchiectasis or its complications. The total number of patients in these groups is 171; tables 2 and 3 give the salient features.

The tables are self explanatory and require little comment. It should be emphasized, however, that the illness of these 171 patients represents bronchiectasis without any known etiologic agent or factor, such as a foreign body or a pulmonary abscess. Since no patient is included who was admitted after December 1935, the diagnosis of disease of the lingula pulmonis is not mentioned. In the early days a diagnosis of bronchiectasis was sufficient, as no surgical intervention was contemplated. However, it is considered mandatory now completely to fill all the bronchial segments with iodized oil before undertaking surgical intervention, and therefore disease of the lingula pulmonis is frequently found. Disease of the sinus was determined by clinical study and roentgen examination or transillumination in every patient, with but 2 exceptions.

12. Cookson, H. A., and Mason, G. A.: Bronchiectasis a Fatal Disease, *Edinburgh M. J.* 45: 844-854, 1938.

Hemorrhage is given as the most frequent complication during the course of the disease, and yet it is a rare cause of death, as may be seen in the tables. The term hemorrhage as used here means that the patient has had either hemoptysis or a frank hemorrhage. Of the 171 patients 67, or 39 per cent, dated the onset of their pulmonary disease from what was called pneumonia. There is little if any evidence to support the belief that bronchiectasis is caused by pneumococcus pneumonia. Other forms of pneumonia are perhaps less well understood, but evidence that they produce bronchiectasis is more likely in view of the changes produced in lung tissue. These patients probably were told that they had pneumonia by their physicians on the basis of fever, signs of consolidation or impaired resonance and rales, a condition probably better termed pneumonitis secondary to bronchiectasis. However that may be, we do not wish to leave the impression that we consider pneumonia as an important etiologic factor in the production of bronchiectasis.

CONCLUSIONS

1. One hundred and seventy-one patients with bronchiectasis admitted to the Jefferson Medical College Hospital between 1925 and 1935 have been studied.
2. Fifty-nine, or 34.5 per cent, are dead from bronchiectasis or its complications.
3. The average duration of life in the dead patients from the onset of symptoms was thirteen and one-half years.

PARAVERTEBRAL SYMPATHETIC BLOCK WITH ALCOHOL FOR THE RELIEF OF CARDIAC PAIN

REPORT OF FORTY-FIVE CASES

ROBERT L. LEVY, M.D.

AND

RICHMOND L. MOORE, M.D.

NEW YORK

There are certain persons who suffer so intensely from frequent paroxysms of cardiac pain that life becomes burdensome. They do not form a large group, but their plight is pitiable. Glyceryl trinitrate affords momentary relief, but they are not helped for any length of time by prolonged rest or by any of the usual medicinal remedies. In the preponderant majority, coronary sclerosis is at the basis of the trouble; a smaller number have aortic insufficiency resulting from either rheumatic fever or syphilis; to a few with no demonstrable anatomic lesions is applied, for want of a better term, the diagnosis "coronary spasm." In all these conditions the available evidence indicates that anoxemia of the heart muscle due to coronary insufficiency is the major factor concerned in causing the pain.

Various surgical procedures have been suggested and tried in the effort to bring relief. Among them may be mentioned cervical sympathectomy, section of the roots of the dorsal nerves, sympathetic ganglionectomy, cutting of the white rami communicantes, total thyroidectomy and the formation of a new supply of blood to the heart. The relative merits of these operations

Read in abstract before the American Clinical and Climatological Association, White Sulphur Springs, W. Va., Oct. 25, 1940.

From the Departments of Medicine and Surgery, College of Physicians and Surgeons of Columbia University, and the Medical and Surgical Clinics of the Presbyterian Hospital.

recently have been subjected to critical analysis¹ and will not be discussed here. In 1931 we reviewed the steps leading up to the development of paravertebral alcohol block by Swetlow,² collected all the cases reported up to that date and added 9 of our own.³ At this time our experiences with 45 patients, including the 9 just mentioned, will be summarized, and the possible effects on the heart of interrupting painful sensations arising in it will be given brief consideration.

CLINICAL MATERIAL

Injections were made on 45 patients who suffered from severe, paroxysmal cardiac pain. Thirty-three were men; 12 were women. In 40, the diagnosis was coronary sclerosis; 3 had aortic insufficiency; 1 woman, whose discomfort was intense, showed no evidence of organic disease over a period of years, and her pain was classified as an instance of "coronary spasm;" 1 man, after seven years of observation, has come to be regarded as a malingerer. A summary including the ages of the patients is given in table 1.

The final analysis of results has been made on the basis of 40 cases. Four patients who died within a month and 1 lost to a follow-up examination have been excluded (table 1). Of these 4 dead, the first was a woman aged 65 with hypertension, who had suffered from a hemiplegic attack two years previously. She died of a cerebral hemorrhage on the day following injection. The second was a man aged 60, whose parox-

ysms were unusually severe and frequent and who died of coronary occlusion on the third day after operation. The third was a woman aged 55, who died on the eleventh day after injection. Necropsy revealed a recent thrombus in the anterior descending branch of the left coronary artery, with fresh infarction of the left ventricle. The fourth was a woman aged 67 who died of granulocytopenic angina which first became manifest thirteen days after injection. The leukocyte count on the day before operation was 9,900; on the day before death it was 800 per cubic millimeter. It seems unlikely that these terminal episodes resulted from the operative procedure.

Of the 40 patients followed, 10 were highly nervous persons who tended to exaggerate their symptoms. All of them showed unmistakable signs of heart disease. Whereas in a few the result was difficult to appraise with any reasonable degree of accuracy, relief, when

obtained, assumed added significance. When there was doubt as to the outcome, an attempt was made to underestimate the possible benefit derived.

POINTS IN TECHNIC

In general, the same technic has been used in all the cases. The needles were inserted in the upper five or, occasionally, six intercostal spaces, as described by White,⁴ and tests were made to be sure that the points were not in the pleural cavity, in blood vessels or in the subarachnoid space. Markers were used to measure the depth to which the needles were inserted, and when the point of each needle reached the lateral aspect of the vertebra or the head of the corresponding rib it was assumed that the correct depth had been attained. In every instance the injection of alcohol was preceded by the introduction of 5 cc. of a 1 per cent solution of procaine hydrochloride. The preliminary injection of procaine hydrochloride prevents the pain which would otherwise be caused by the irritative effects of alcohol. Five cc. of an 80 per cent solution of alcohol was injected through each space in almost all our patients. In a few 6 cc. was used. In 1 patient 10 cc. was injected through each of the upper seven spaces; this caused more than the usual amount of postoperative discomfort. After the injection of procaine hydrochloride the patients were examined for signs of sympathetic and intercostal nerve block. Whether or not these signs were evident, the alcohol was injected unless there had been some difficulty in inserting the needles. This was done because it was found that the immediate appearance of a satisfactory effect of procaine hydrochloride was not essential to a successful result. Sometimes, signs which could not be satisfactorily demonstrated immediately after the procaine hydrochloride was injected were easily recognized the next day. Furthermore, many patients, because of temperament, difficulty with language, drowsiness or ignorance, were unable to aid in the mapping of areas of anesthesia. Some of them would never have consented to another attempt, and few could have cooperated any better the second time.

In the beginning it was our practice to perform all injections with the patient on the operating table. The patients were transported to and from the operating room by stretcher and were put back to bed immediately after the injection. More recently, in accordance with White's suggestion, this practice was discontinued. Each patient was given the injection in his own bed and required to lie quietly for at least one hour after injection. According to White, this is important to prevent diffusion of the alcohol and irritation of outlying nerves. So far, our experience does not seem to show that the results are any better in the patients treated in this manner. One important advantage of the operating table is that it can be raised or lowered to suit the operator's convenience.

RESULTS⁵

The variability of the clinical course in patients with coronary sclerosis is well known. In many, spontaneous improvement occurs over a period of time, presumably as the result of the development of a collateral circulation; in others symptoms increase as the disease

5. The material was subjected to detailed statistical analysis with the help of Miss Dorothy Kurtz, supervisor of the record department of the Presbyterian Hospital.

progresses. All our patients were under observation for a sufficient length of time to indicate that they were getting worse rather than better. When improvement occurred it appeared in direct relationship to alcohol block.

Of the 40 patients 77.5 per cent (31) experienced varying degrees of improvement; no relief was obtained in 22.5 per cent (9). In 47.5 per cent (19) improve-

Six to seven years.....	6
Two to five years.....	6
One year or less.....	8

ment was permanent to the time of the last follow-up examination. In 40 per cent (16) relief was marked, in 5 per cent (2) it was moderate and in 2.5 per cent (1) it was slight. Temporary relief was obtained in 30 per cent (12). This was marked in 15 per cent (6) and moderate in 15 per cent (6) (table 2). By marked improvement is meant 75 to 95 per cent relief, by moderate improvement 50 to 75 per cent relief, and by slight improvement 25 to 50 per cent relief.

Of the patients with permanent relief, 2 were followed for nine years, 6 for from six to seven years, 3 for from two to five years and 8 for one year or less (table 2). Of the 12 patients with temporary relief, the pain always recurred in a year or less: in 3 in less than one month, in 2 in from one to five months, in 2 in from six to eleven months and in 5 in one year.

In 18 cases relief was immediate, in 5 it was delayed less than one month, in 2 it occurred at the end of a month and in 1 at the end of two months.

Neither the duration of symptoms nor a previous history of coronary occlusion nor the degree of incapacity prior to injection appeared to influence the outcome. Ten patients in whom relief was marked and permanent had had pain for more than two years; of these, 6 had had symptoms for five years or more.

The electrocardiogram prior to injection was fixed in 16 cases and changing in 14; in 10 cases only one record was taken. That the form of the electrocardiogram was undergoing modification presumably indicated altering conditions in the coronary circulation. In these two groups improvement occurred with equal frequency. After injection the electrocardiogram remained unchanged in 12, improved in 7 and became worse in 10; in 11 cases only one record was taken. In every instance in which the electrocardiogram improved, relief was obtained. However, relief was observed also in patients in whom there was no change in the form of the records or whose records indicated advancing lesions.

After injection, Horner's syndrome appeared in only 9 patients, of whom 6 obtained relief. It was absent in 31 patients, of whom 25 obtained relief. It is clear that the occurrence of Horner's syndrome was not essential to a successful result.

Many of those who were relieved were able to go to work, either resuming their former occupation, working part time or at a less strenuous job than before. For all the patients who obtained permanent relief the amount of glyceryl trinitrate required was materially reduced; for 5 of these none was required.

Ten patients were dead at the time this material was assembled (table 3). Seven of them died of coronary occlusion at varying intervals following injection. In 1 case the cause of death was not known; in 1 case of rheumatic aortic insufficiency, death occurred from congestive heart failure; in a third, an operation for intestinal obstruction was followed by gangrenous peritonitis. It is at once apparent that coronary occlusion was the most frequent cause of the ultimate fatal outcome, as might have been anticipated.

There is a noticeable difference in the results in the private patients and those in wards. Of 9 private patients, all obtained relief; 6 of them obtained marked permanent relief. Of 30 ward patients, 22 obtained relief; 10 obtained marked permanent relief. As a group, the private patients were less inclined to be psychoneurotic; perhaps their social status eliminated the factor of economic worry. Their better intelligence made it easier to appreciate the degree of their discomfort as well as the extent of their relief.

In 2 cases a second injection was done. One patient was markedly improved for about a year after the first injection and then begged for a repetition of the procedure. She obtained almost complete relief after a second injection on the same side. Another patient was given a second injection after an interval of three weeks because the first was without result. He obtained no relief, and there was some question, in spite of unmistakable clinical evidence of coronary sclerosis, as to whether he was addicted to morphine.

In only 2 patients did the pain radiate solely to the right. In both of these, injection was done on the right side with a good result in 1 and a fair one in the other. In 18 cases there was radiation to both sides but predominantly to the left. Injections were made into the left side, with the result comparable to that obtained

when radiation was on one side only. After relief of pain on the left side there was never a shift of discomfort to the opposite half of the chest.

UNTOWARD EFFECTS

In 38 patients, painful alcoholic neuritis of the intercostal nerves was observed after the injection. This was severe in only 3 instances. In 14 cases it lasted less than a month and in 12 for about two months. In 12 cases it persisted for three months or more. Eventually it always disappeared; and, whereas it was a cause of complaint, the relief of cardiac pain, when

obtained, more than compensated for discomfort. The neuritis was accompanied by partial temporary anesthesia or hypesthesia of the wall of the chest. In 5 cases a small pleural effusion developed which was always absorbed within a week; aspiration was never necessary. One patient complained of pleuritic pain. Pneumothorax, reported by others,⁶ was not observed. After injection, increased temperatures occurred in 25 patients and ranged from 99 to 104 F. Fever never lasted more than four days unless complicated by pleural effusion.

COMMENT

It is apparent that in a high percentage of cases paravertebral alcohol block afforded relief from pain. There was no immediate operative mortality. Our results are similar to those of White,^{6a} though the percentage of successes is not quite as large. He failed in only 9.5 per cent of 62 reported cases; the result was good in 52 per cent and fair in 30.5 per cent; in 8 per cent death occurred within two weeks of injection.

Several observations deserve comment. In not 1 of our patients was relief complete. Even in those in whom a result was obtained which was satisfactory to the patient some form of discomfort persisted. If the patient's tolerance for physical activity was exceeded or if he became emotionally upset, there appeared either actual twinges of pain, of less intensity than before injection, or a sense of pressure beneath the sternum. Some of the patients described this as a feeling of congestion in the chest. In several, mild dyspnea or a sinking sensation in the epigastrium was substituted for pain. That there should be some persistence of a danger signal is perhaps desirable, for the patient is warned when he has overtaxed his coronary reserve.

The question as to why relief should always be partial and in varying degree is not easy to answer. It is conceivable that the sympathetic ganglions and their rami communicantes are not completely destroyed. Should some of these again become capable of functioning, through a process of repair, a return of pain might be anticipated and, indeed, did occur in some instances. That relief should occur immediately is due to the prompt action of the alcohol on the nervous tissues. In those cases in which relief was delayed, perhaps degeneration took place more slowly. Failure to afford relief may be due either to faulty technic in injection, as a result of which the ganglions and rami are not adequately infiltrated, or to the conduction of pain by accessory pathways, some of which, as yet, are not known. It was striking to observe that even those patients who had obtained marked relief for varying periods and then suffered from an attack of coronary occlusion experienced intense pain at the time of the closure of the coronary vessel. This was invariably so, and the pain was referred chiefly to the area of the original discomfort. If the nervous pathways were completely interrupted, the attack should be painless; to assume that there are differences in the intensity of the impulses themselves does not furnish a wholly satisfactory answer. In this connection it is worthy of note that in the dog, in order to permit of painless ligation of a coronary branch, sympathetic denervation

of the heart on both sides is necessary;⁷ and even under these conditions, pain occasionally is felt.⁸

In an earlier paper we³ pointed out that the appearance of Horner's syndrome was not essential for obtaining a good result. This observation has been amply substantiated in this larger series of cases, for the syndrome appeared in a comparatively small number of those who experienced the most marked relief. According to current knowledge, afferent fibers carrying painful impulses from the heart reach the central nervous system by way of the first five thoracic ganglions, rami communicantes and dorsal roots.⁷ If this path is interrupted there should be no perception of painful stimuli having their origin in the heart or its blood vessels, and the destruction of the stellate ganglion, which causes the appearance of Horner's syndrome, should not be required.

It is tempting to speculate as to the possible effect of abolishing pain on the coronary circulation and on the heart itself. Recently the experimental work of Manning, McEachern and Hall⁹ has thrown interesting light on this matter. They first showed that the mortality following sudden occlusion of the anterior descending branch of the left coronary artery, in the anesthetized dog, is less than 10 per cent, whereas in the conscious dog it is about 40 per cent. Sudden occlusion of the left circumflex branch, under anesthesia, resulted in a mortality of 25 per cent, whereas in the conscious animal it was 75 per cent. The animals which died all showed ventricular extrasystoles, tachycardia and terminal ventricular fibrillation. It was concluded that the great increase in mortality for the conscious animal might be due to a reflex spasm of collateral arterioles and small arteries, producing additional areas of ischemia.

In a second paper these authors⁸ observed in dogs that, when the stellate and upper five thoracic ganglions had been removed on the left side, ligation of the left circumflex branch in the conscious state resulted in a mortality of 33 per cent and ventricular fibrillation did not occur in any of the animals. When this same branch was ligated after bilateral sympathetic denervation of the heart, the mortality rate was 9 per cent. When the left anterior descending branch was ligated after sympathetic denervation on both sides the mortality was zero. Extrasystoles were infrequent, and ventricular fibrillation was not seen. These experiments were regarded as furnishing additional evidence that, by preventing afferent impulses from reaching the vasoconstrictor center, reflex spasm of collateral coronary arteries is prevented. It was suggested also that sympathetic denervation may render the myocardium less susceptible to the onset of ventricular fibrillation. Perhaps both mechanisms are concerned.

Clinical observations parallel those made in the laboratory. Of 376 patients who died of coronary sclerosis and thrombosis and were examined post mortem at the Presbyterian Hospital, 14 per cent died suddenly.¹⁰ In the group with pain death was sudden in 27.5 per cent, and in the group without pain in only 9.1 per cent.

Regardless of the character and extent of the coronary lesions, the presence of pain tripled the incidence of sudden death.

Two cases are briefly presented to show the course of patients who obtained marked permanent relief and also to illustrate the changes in the form of the electrocardiogram which were observed after alcohol block:

Fig. 1 (case 1).—Electrocardiograms of a woman aged 45 who has obtained marked permanent relief for more than six and one-half years. She is still living. The precordial lead in A and B was taken according to the old technic, with which the T wave in lead 4 is normally inverted; in C, it was taken with the newer technic and corresponds to lead 4 F. A, Jan. 16, 1934. (A record taken two weeks earlier was identical.) On January 18, paravertebral block was done. B, March 3 (six weeks after injection). C, Sept. 9, 1940.

REPORT OF CASES

CASE 1.—J. T., a housewife, aged 45, first came to the hospital in October 1933 complaining of attacks of precordial pain for thirteen weeks. These had been so severe and frequent that she had been unable to do her housework. Save for mastectomy for chronic cystic mastitis, she had always been well prior to the present illness. The pain radiated to the left arm and to the left side of the jaw. There was no dyspnea. Glyceryl trinitrate afforded relief.

Examination showed slight enlargement of the left side of the heart. The sounds were distant. No gallop was heard. The blood pressure was 100 systolic and 60 diastolic. The electrocardiogram showed sinus rhythm, with low voltage; the T wave was inverted in lead 1. The Wassermann reaction of the blood was negative. The blood cell count was normal.

From Oct. 31, 1933 to Jan. 18, 1934 the patient was in the hospital in bed. There were frequent and severe attacks of pain, requiring as many as nineteen tablets of glyceryl trinitrate in twenty-four hours. Discomfort increased in severity, in spite of rest during this period, and the electrocardiogram showed changes in form which at no time indicated infarction. The T wave in lead 1 was, on occasion, deeper, and the T wave in lead 2 was inverted. Records made on January 2 and January 16, however, were identical (fig. 1 A).

On Jan. 18, 1934 paravertebral alcohol injection was done through the upper six thoracic interspaces of the left side. Horner's syndrome was noted on the following day. There was mild intercostal neuritis, which lasted for two months. Relief of paroxysms of cardiac pain was immediate, though not complete. The number of glyceryl trinitrate tablets taken during the next few weeks ranged from one to five. By February 4, none were required. An electrocardiogram taken six weeks after injection showed an upright T wave in lead 1, a T wave in leads 2 and 3 of greater amplitude and an increase in the voltage of the QRS complexes (fig. 1 B).

This patient has been followed at regular intervals for the past six years and nine months. There has been progressive improvement. On Oct. 1, 1940 she was averaging less than one glyceryl trinitrate tablet daily and this only on making some

unusual effort. There was no actual pain but only a choking sensation. She was doing her own housework. The blood pressure was 128 systolic and 65 diastolic. The electrocardiogram was normal (fig. 1 C).

CASE 2.—A. L. S., a man, aged 58, an architect, was referred in January 1930 by Dr. A. B. Morrill, of Bronxville, N. Y. He had been well up to five years previously, when paroxysms of substernal pain first appeared after effort. The attacks became so much more frequent and intense that in July 1929, about seven months before he was seen by us, he was put to bed for a long rest. Since then he had been out of business, at home most of the time and going downstairs only occasionally.

Examination showed no cardiac enlargement. The sounds were distant, but no gallop was heard. There was a short systolic blow at the apex. The blood pressure was 136 systolic and 74 diastolic. The electrocardiogram showed a diphasic T wave in lead 2 and inversion of the T wave in lead 3 (fig. 2 A).

On March 7 he was admitted to the Presbyterian Hospital. There a duodenal ulcer was discovered by roentgen examination and he was given a Sippy regimen. The attacks of cardiac pain continued and were caused by such slight exertions as shaving or even turning in bed. These pains were relieved by glyceryl trinitrate.

On March 19 paravertebral alcohol injection was made through the first five left dorsal interspaces. Horner's syndrome did not develop. There was some immediate partial relief. The electrocardiogram taken one week later showed an upright T wave in lead 2 (fig. 2 B). At the end of two months he was markedly improved. The duodenal ulcer, as shown by roentgen examination, had completely healed. By October 30 he was able to go up and down stairs twice a day without discomfort. For as long as two weeks at a time he did not take glyceryl trinitrate. He went motoring and was able to walk from four to six blocks on the level.

In May 1931 he began going to business and commuting from Bronxville to New York by train. There was a little substernal pressure at times, particularly when he bent over to tie his shoes or after his bath.

In June 1932 he stated that there had been no severe pain for a year and that he had not seen a physician during this period. He had not taken glyceryl trinitrate for ten months. Improvement was continuing.

In June 1933 he said that he was "getting better all the time." He had taken only one glyceryl trinitrate tablet in twenty months and this after walking in a wind. There were, however, slight twinges of precordial discomfort, chiefly when he moved about within an hour after a meal. He had gained 11 pounds

Fig. 2 (case 2).—Electrocardiograms of a man aged 58 who obtained marked permanent relief until his death from coronary occlusion more than six and one-half years after injection. A, March 15, 1930. (A record taken one week earlier was identical.) On March 19, paravertebral block was done. B, March 27 (eight days after injection). C, June 18, 1934.

(5 Kg.) in the past year. The blood pressure was 136 systolic and 80 diastolic. The electrocardiogram remained normal (fig. 2 C).

He continued to work regularly until the day before his death. On Thanksgiving Day 1936, while at dinner carving the family turkey, he suddenly had intense substernal pain and went into shock. He died within twelve hours and in the opinion of his physician had a terminal coronary occlusion.

The electrocardiograms of these 2 patients showed modifications in the T waves occurring respectively six weeks and one week after injection. Coincidentally with progressive improvement, the electrocardiograms became normal and remained so in both cases for more than six years. A similar modification in the form of the graphic record was reported by Raney,¹¹ after cutting the second, third, fourth and fifth rami communicantes and sectioning the sympathetic chain between the fifth and sixth dorsal ganglions on the left side. The patient had suffered from severe cardiac pain due to disease of the coronary arteries and obtained complete relief. On the second day after operation, the T wave in lead 1, which had been negative, became upright. Such changes in the electrocardiogram furnish at least suggestive support to the experimental observations of Hall and his collaborators, to which reference has already been made. It seems unlikely that reversal in the direction of the T waves occurring so soon after operation is the result of anatomic changes in the heart. It is more probable that they are due to an altered physiologic state of the coronary circulation, possibly due to release of spasm. If vasoconstriction was thus permanently diminished or abolished, an increase in coronary flow might be anticipated. Perhaps, therefore, interruption of the sensory pathways for pain not only brings relief to the patient but, over a period of time, results in an improvement in the supply of blood to the heart. Should this concept prove to be valid, relief from painful discomfort earlier in the course of coronary disease might be expected to exert a favorable influence on its course. Whether, in any of these advanced cases, life was prolonged, it is not possible to say. Certainly, in them, unilateral alcohol block did not prevent the occurrence of coronary occlusion or of sudden death.

SUMMARY AND CONCLUSIONS

1. Forty-five patients with severe paroxysms of cardiac pain, due in thirty-six instances to coronary sclerosis, were given paravertebral injections of alcohol. Four patients died within three weeks and 1 was lost to follow-up examination, so that the final analysis was based on 40 cases. Relief was obtained in 77.5 per cent; in 22.5 per cent treatment failed to give relief. The relief was marked and permanent in 47.5 per cent of the total number. Eight cases have been followed for more than six years; 2 of these have been followed for nine years.

2. There was no immediate operative mortality. In 5 cases pleural effusion developed on the left side; the fluid was absorbed without aspiration within a week. Most of the patients suffered from painful intercostal neuritis, which lasted from a few weeks to several months.

3. Many of these patients who had been bedridden or confined to the house were able to resume an active life.

4. The appearance of Horner's syndrome was not essential for a successful result.

5. Changes in the form of the electrocardiogram in the direction of normal suggest that interruption of the sensory pathways, in certain cases, may diminish or abolish spasm in the coronary bed. This is to be regarded as a desirable effect, tending to promote a more adequate collateral flow in unaffected vessels. On

the basis of this evidence and in view of experiments on dogs, it is suggested that interruption of pathways for pain not only affords relief to the patient but may exert a beneficial effect on the coronary circulation. Under these circumstances, earlier relief of pain in patients with coronary sclerosis might be expected to influence the course of the disease in a favorable manner. In the cases of more advanced coronary disease here reported, unilateral block with alcohol did not prevent the occurrence of coronary occlusion or of sudden death.

THE EFFECT OF DEPRIVING THE INFANT OF ITS PLACENTAL BLOOD

ON THE BLOOD PICTURE DURING THE
FIRST WEEK OF LIFE

Q. B. DeMARSH, M.S., B.M.

H. L. ALT, Ph.D., M.D.

AND

W. F. WINDLE, Ph.D.

WITH THE COOPERATION OF

DAVID S. HILLIS, M.D.

CHICAGO

Although much has been written concerning the blood of the infant, knowledge of the early postnatal blood picture including changes at birth and during the first week of life is incomplete and controversial. Our interest in the blood of the newborn was stimulated by the numerous recent reports on collection of placental blood for "blood banks." Those who have advocated the use of placental blood for transfusion purposes,¹ have failed to recognize possible deleterious effects on the infant when it is deprived of this blood. It is essential to clamp the umbilical cord immediately after birth in order to salvage an adequate amount of placental blood. Even when placental blood is not collected, the practice of clamping the cord promptly at birth is a rather common one.

It is natural for the newborn infant to retrieve most of the blood in its placental circulation if severing of the cord is delayed for a sufficiently long time. Haselhorst and Allmeling² found that the average amount of blood in the placental vessels of 120 infants was 104 cc. They showed that 51 per cent of this flowed into the infant from the placenta in the first minute

From the Departments of Anatomy and Medicine, Northwestern University Medical School, and from the Cook County Hospital.

This study was made possible by a grant-in-aid of research from the John and Mary R. Markle Foundation to Dr. Windle. The staff of the Passavant Memorial Hospital cooperated in obtaining supplementary data.

after delivery, 79 per cent reached the child in the first five minutes and 91 per cent in the first ten minutes. Goodall and his colleagues³ obtained an average of 125 cc. of blood from the placenta for use in a blood bank. Grodberg and Carey⁴ salvaged a maximum of 215 cc. of placental blood from one patient.

The actual total volume of blood of the human fetus and its placenta has never been determined, but in sheep, according to Barcroft and Kennedy,⁵ it is about 150 cc. per kilogram, or 15 per cent of the body weight of the fetus alone. About one fourth of this blood was in the placental circulation near term. Lucas and Dearing⁶ estimated the blood volume of human infants by the vital dye method. They obtained an average of 531 cc. of blood from 12 newborn infants three to twenty-four hours after birth. This was 15.5 per cent of the body weight. Therefore the loss of 125 cc. of placental blood deprives the child of about one fourth (24 per cent) of its total blood volume. Such a great blood loss to the infant, even though performed for a good cause, should be viewed with alarm.^{6a}

Our purpose in the present study was to find out whether deprivation of the infant of its placental blood by tying of the cord immediately at birth influenced the red corpuscle count and hemoglobin content of the blood during the first week of life. In reviewing the voluminous literature on the blood picture in the newborn one finds that the time at which the umbilical cord was clamped is seldom stated, that the source of the blood and method of taking the sample are often omitted, that the methods of estimating hemoglobin vary widely and that the hemoglobin content, frequently reported in percentage, cannot always be transposed into grams per hundred cubic centimeters. The average figures reported for the number of red corpuscles and the amount of hemoglobin vary all the way from those encountered in normal adults to values as high as 6.5 million red corpuscles per cubic millimeter and 23 Gm.⁷ of hemoglobin per hundred cubic centimeters. Individual counts greater than 7 million are not uncommon. Many investigators have noted a slight rise in red corpuscle and hemoglobin values during the first few days of life.

Only a few investigators⁸ have studied the effect of early and late clamping of the umbilical cord on the blood picture of the infant. Their results are listed in table 1. Individually the data are incomplete and for the most part insignificant from a statistical point of view, but impressiveness is gained by assembling them. The figures clearly indicate a relationship between the time of ligation of the umbilical cord and the blood

picture, for red corpuscle and hemoglobin values were uniformly higher when the infants were allowed to retrieve placental blood at birth than when deprived of it by early clamping of the cord. Our own results demonstrate this fact even more clearly.⁹

PROCEDURE

The present study was performed on normal infants at the Cook County Hospital. One of us (Q. B. D.) was present at each delivery. All but two deliveries were conducted without anesthesia and with no medication previous to the third stage. Except when noted in the tables, the deliveries were normal in every way including their duration.

Red corpuscle counts were made with Bureau of Standards equipment and hemoglobin determinations with a Hellige-Sähli apparatus calibrated by the oxygen capacity technic. Blood studies were made on venous blood of the mothers during labor. Anemia was present in only 1 mother and was slight. The cords were

* Exact time of tying cord unknown.

clamped as soon after delivery as possible in one series of 25 newborn infants (table 2); the average time elapsing was thirty seconds or less. In another 25 infants (group A in table 3) the cords were not clamped until the placenta had separated from the uteri. This usually occurred within ten minutes after delivery. It was found that the baby receives an additional amount of blood between the time the cord stops pulsating and the time the uterus contracts firmly with separation of the placenta. The blood in ten placentas was collected and measured at the end of pulsations (about three minutes after birth) and was found to average 62.4 cc.¹⁰ Only a few cubic centimeters of blood at best can be obtained from the umbilical cord after separation of the placenta. In fact, we were unable to draw enough blood from a number of the cords to give adequate determinations of hemoglobin and corpuscles. In a supplementary series of four infants (group B in table 3) the clamping was delayed two to eight minutes,

6a. We are at present studying the blood volume of newborn infants by the Evans blue method and find it to be much lower (10 per cent of body weight) than reported by Lucas and Dearing.⁶ The placental blood therefore is probably equal to an even greater percentage of the blood volume of the infant than indicated above.

7. According to adult standards, 15 Gm. of hemoglobin equals approximately 100 per cent.

10. Pulsations indicate that the arterial channels to the placenta are unoccluded. Cessation of pulsation is not an indication that the placental vessels have emptied themselves of blood. Expulsion of blood from capillaries and veins of the placenta into the infant appears to be accomplished by uterine compression of the placenta as well as by vasoconstriction of its vessels.

but for one reason or another birth conditions seemed to fit neither of the two strictly defined categories. The averages of all 29 delayed cases are approximately the same as those of group A alone and were used in construction of chart 1.

Red corpuscle counts and hemoglobin determinations were made on umbilical cord blood and on blood from the infant taken twenty to seventy-five minutes, one day, three to four days and six to seven days after birth. Blood samples were obtained from the heel of the infant; the stabs were sufficiently deep to allow the blood to flow freely without squeezing the heel. Analyses were made promptly after the blood was drawn.

Daily reticulocyte counts were made in six newborn infants whose cords were clamped early and in six

Chart 1.—Graphic reproduction of the average number of red corpuscles, amount of hemoglobin and body weight of infants from birth to the seventh day. Solid lines connect values for infants whose cords were clamped immediately; broken lines, the values after delayed clamping.

whose cords were clamped late. The reticulocyte preparations were made by placing a small drop of blood between two cover slips covered with films of brilliant cresyl blue. In about two minutes the slips were pulled apart, allowed to dry and stained by Wright's method. To estimate the percentage of reticulocytes, 500 corpuscles on each of two cover slips were examined.¹¹

RESULTS

Red Corpuscles and Hemoglobin.—The result of the red corpuscle counts and hemoglobin estimations are recorded in tables 2 and 3. Averages are shown graphically in chart 1. The average values for cord

blood were 4.48 million red corpuscles per cubic millimeter and 15.7 Gm. of hemoglobin per hundred cubic centimeters. They were approximately the same whether the cord was clamped early or late. Within twenty to seventy-five minutes after birth the red corpuscle and hemoglobin values in blood from the heel were much higher than in the blood obtained from the umbilical cord. Thenceforth throughout the week the infants whose cords were clamped early had significantly lower corpuscle and hemoglobin values than did those whose cords were clamped late. During the first week the former group averaged 5.45 million red corpuscles per cubic millimeter and 19.5 Gm. of hemoglobin per hundred cubic centimeters, whereas the latter group averaged 6.01 million red corpuscles and 22.1 Gm. of hemoglobin. The difference between the two groups at each age period was statistically significant, as may be seen in table 4. It was more significant in respect to number of corpuscles at one, three to four and six to seven days after birth than on the day of birth. A peak was reached in the hemoglobin value at three to four days in both series of infants. It was not accompanied by a rise in number of red corpuscles.

The difference in number of red corpuscles and amount of hemoglobin between blood from the cord and that from the heel of the infant within an hour after birth is truly surprising.¹² We thought that there might be a discrepancy between capillary and venous blood. This was suggested by several observations in the literature. Waugh and his colleagues¹³ reported 15 to 15.5 Gm. of hemoglobin in blood from umbilical cords as well as from venous sinuses during the first week of life. The umbilical cords were usually tied after pulsations had ceased. Osgood,¹⁴ who tied the cords immediately after birth, found on the average 17.2 Gm. of hemoglobin per hundred cubic centimeters of venous sinus blood during the first four days. This declined to 16 Gm. by the tenth day. Red corpuscles averaged 4.6 million per cubic millimeter during the first ten days of life. These values do not differ greatly from our own results on umbilical cord blood but they are considerably lower than those we obtained from blood taken from the heel.

Haden and Neff¹⁵ compared capillary and venous sinus blood of newborn infants. They found red corpuscles more numerous in capillary blood. Duke and Stofer¹⁶ discovered a similar discrepancy between capillary and venous blood of patients with pernicious anemia. This blood, like that of the newborn, contains many large corpuscles. They suggested that these macrocytes occluded capillaries and led to concentration of the corpuscles there. Other investigators have failed to confirm the difference between capillary and venous blood of the newborn.¹⁷

We have made comparisons between samples obtained from the superior sagittal sinus (or jugular vein) and from the heel capillaries of six normal infants, as well as between cubital vein and finger blood from one adult with pernicious anemia. Our results, recorded in table 5, show little difference between capillary and venous blood in respect to the number of red

12. Recent studies on development of the blood picture in prenatal and postnatal life of the cat have demonstrated a similar although considerably smaller rise in number of red corpuscles at birth than that observed in infants (Windle, W. F.; Sweet, Marion, and Whitehead, W. H.: *Anat. Rec.* 78: 321-332 [Nov. 25] 1940). All the blood samples were drawn from veins in these experiments.

corpuscles. The hemoglobin values obtained in venous blood of infants are comparable with the averages of those obtained in capillary blood (tables 2 and 3).

It is doubtful whether the sudden increase in the number of red corpuscles in the infant's circulating blood at the time of birth is due entirely to a difference between capillary and venous blood. Postnatal dehydration is an unlikely explana-

cytes. The reticulocyte count has been found by most authors²² to average about 4 to 6 per cent at birth. It decreases to less than 1 per cent by the end of the first week. A slight rise in reticulocytes on the second day of life has been noted by Wollstein²³ and by Waugh and his colleagues.¹³ Apparently no one has made comparative studies of the reticulocyte count in the newborn after early and after late tying of the cord. Our results in such a study are recorded in table 6. Averages are shown graphically in chart 2. When the umbilical cord was tied immediately, reticulocytes reached an average peak of 8.6 per cent at twenty-four hours and then decreased slowly. They did not fall below 6 per cent until the fifth day. When tying of the cord was delayed, reticulocytes averaged 5.8 per cent at their peak in twenty-four hours and then fell to 4 per cent by forty-eight hours. A more active blood formation when the cord is clamped early than when it is clamped late is suggested by the higher and more sustained rise in reticulocytes in the former group.

tion, because the change often occurs in less than half an hour. A possible explanation may be found in the relationship of the spleen to this phenomenon. Polycythemia due to splenic contractions during emotional excitement has been observed in the cat.¹⁸ In prenatal life the smooth musculature of the fetal body is relatively inactive in comparison with that of the individual after birth.¹⁹ The smooth muscle of the lamb's spleen begins to contract at birth.²⁰ Perhaps this throws a significant reserve of concentrated corpuscles into circulation. This could cause a rise in red corpuscles at birth. It is interesting to note that Horváth and Hollósi²¹ observed more red corpuscles and hemoglobin in blood from the infant's umbilical artery than in that from the umbilical vein; blood drawn from the heel at birth showed even higher values. The course of blood circulating from the spleen to the heart and thence to the aorta and its branches is such that an increase in corpuscular concentration would manifest itself in the arteries before it would appear in the umbilical veins leaving the placenta.

Reticulocytes.—Toward the end of the present study it occurred to us that depriving the infant of placental blood might result in increased erythropoiesis and that this would be reflected by an increase in the reticulo-

Blood drawn only about an hour after birth from infants whose cords had been clamped immediately contained more reticulocytes than did the blood from the other group. This is not surprising if our theory of splenic contraction at birth is true. The demand on the splenic reservoir may be greater in infants deprived of placental blood than in those getting it. Many of the corpuscles poured into the circulation from the spleen may well be reticulocytes.

Jaundice.—It has been suggested by Franklin²⁴ that delayed clamping of the cord results in greater incidence of jaundice than early clamping. Few infants of our series had jaundice which could be easily determined by inspection. In fact, it was recorded in only 3 of the 25 infants whose cords had been clamped immediately, 5 of the 25 whose cords had been clamped late and 2 of the 4 infants placed in the special

group (B in table 3). Jaundice is probably a normal phenomenon in most instances.

Weight.—Several earlier investigators, according to Schiff,²⁵ claimed that infants whose cords were cut late had less loss of weight and more rapid gains to the original birth weight than did those whose cords were cut early. The average weights of the two groups of infants in the present study ran parallel during the first week of life (chart 1).

It is worth mentioning that Schiff²⁵ found an increased excretion of nitrogen in infants whose cords were cut early. He concluded that the placental blood acted as a source of nourishment which protected infants against the breakdown of body protein.

COMMENT

Deprivation of the infant of placental blood by clamping the umbilical cord immediately results in significantly lower values for red blood corpuscles and hemoglobin during the first week of life than are encountered when clamping is delayed. In addition, there is an increase in the number of reticulocytes in the blood; this indicates an increased demand for blood on the part of the infant. The placental blood normally belongs to the infant, and his failure to get this blood is equivalent to submitting him to a rather severe hemorrhage.

One can easily imagine that loss of as much as 25 per cent of the total blood volume in the newborn infant, as described earlier, may sometimes be critical. Failure to receive the placental blood may be especially harmful to infants born prematurely, to infants after a long, difficult labor and to infants suffering from some pathologic condition. Engel,²⁶ in the latter part of the nineteenth century, reported twice as great mortality in premature infants whose cords were tied early as in those whose cords were tied late. This is understandable because the placenta reaches maximum relative size at about the fifth month and contains a greater proportion of the fetal-placental blood volume in premature infants.

Deprivation of the placental blood also results in a relatively large loss of iron to the infants. Fullerton²⁷ and Stearns and McKinley²⁸ have recently called attention to the fact that the principal iron reserve of the newborn infant is in the circulating hemoglobin rather than in the tissues. Iron liberated during destruction of blood is stored in the tissues and utilized as needed for hemoglobin formation. The amount of iron lost to the newborn infant in 125 cc. of placental blood is sufficient to raise the hemoglobin in a 4 months old infant from 8.7 Gm. to 12 Gm. per hundred cubic centimeters.²⁹ Therefore it seems possible that loss of placental blood may be a factor predisposing infants to anemia during the nursing period.

28. Stearns, Genevieve, and McKinley, J. B.: *J. Nutrition* 13: 143 (Feb.) 1937.

29. Calculation:

Blood in placenta = 125 cc.; hemoglobin 16 Gm. per hundred cubic centimeters; hemoglobin = 0.335 per cent iron

Total iron in placental blood = $1.25 \times 16 \times 0.00335 = 67$ mg.

Infant age 4 months: Average weight = 5.5 Kg.; blood volume = 10.9 per cent;³⁰ hemoglobin = 12 Gm./100 cc.

Total circulating hemoglobin iron = $5.5 \times 10.9 \times 12 \times 0.00335 = 241$ mg.

Total circulating hemoglobin iron minus iron in placental blood ($241 - 67$) = 174 mg.

Theoretic hemoglobin of infant (depleted of iron reserve) deprived of the amount of iron present in placental blood.

$\frac{174}{241} \times 12$ Gm. = 8.7 Gm. per hundred cubic centimeters

It is our opinion that enough evidence is now available to condemn the practice of clamping the umbilical cord promptly after birth and incidentally to condemn the use of placental blood for transfusion purposes. A delay on the part of the obstetrician in clamping the cord, not only until pulsations cease but also until the placenta has separated from the uterus, will give the newborn infant the quota of blood that naturally belongs to him.

CONCLUSIONS

1. Deprivation of the infant of the portion of its blood that is in the placenta by clamping the umbilical cord immediately after birth influences the red corpuscle count and hemoglobin content of the blood during the first week of life. Those infants whose cords were not clamped until the placentas had separated from the uteri had on the average 0.56 million more red blood corpuscles per cubic millimeter and 2.6 Gm. more hemoglobin per hundred cubic centimeters during the first week than those whose cords were clamped immediately.

Chart 2.—Graphic reproduction of the average percentage of reticulocytes in the blood of infants from birth to the seventh day. Solid lines connect values for those whose cords were clamped immediately; broken lines, the values after delayed clamping. Six infants are represented in each series; had subject 26 D been omitted, a somewhat more striking difference between the two curves would have resulted.

2. Blood drawn from the infant's heel twenty to seventy-five minutes after birth had significantly higher red corpuscle and hemoglobin values than blood drawn from the umbilical cord at birth. It is possible that the spleen plays a part in bringing on this polycythemia of birth.

3. Higher reticulocyte counts in infants whose cords were clamped immediately suggested a greater demand for blood in this group than in the group whose cords were not clamped until placental separation.

4. Early clamping of the umbilical cord is equivalent to submitting the child to a hemorrhage at birth.³⁰

303 East Chicago Avenue.

30. Since this article was submitted for publication many more determinations of the red corpuscles and hemoglobin have been made simultaneously on sinus and heel blood of newborn infants. Contrary to our first few observations, we find the values to be consistently lower in sinus blood. The difference in number of red corpuscles and amount of hemoglobin between the immediate and delay groups is similar to that found in capillary (heel) blood. The red corpuscles and hemoglobin in sinus blood show a sharp rise within an hour after birth in the delay group but not in the immediate group. Reticulocyte percentages in sinus blood in the two groups show the same difference found in capillary blood. These results will be reported in detail in a subsequent publication.

A CONTROLLED CLINICAL TEST OF
INFLUENZA A VACCINE

GILBERT DALLDORF, M.D.
ELINOR WHITNEY
AND
ARTHUR RUSKIN, M.D.
VALHALLA, N. Y.

During late January 1941 a small epidemic of influenza occurred among the employees of Grasslands Hospital, one half of whom had been vaccinated with the "complex chick embryo influenza A vaccine" developed by Horsfall and Lennette.¹

Chart 1.—Case incidence of influenza among vaccinated and non-vaccinated employees.

Vaccine had been administered to 415 of 826 employees of the institution on December 11 and 12. Scattered cases of influenza appeared several weeks later. The epidemic reached its peak during the seventy-two hours commencing January 31, at which time 32 of the 77 identified cases were reported (chart 1). Of the 77 employees who contracted the disease 32 had been vaccinated and 45 had not. Every patient was examined by us, and whenever possible blood samples were taken during the acute stage of the disease and again during convalescence.

No effort was made to recover the virus, one of our purposes being to institute simple and inexpensive procedures which would suffice to diagnose cases of suspected influenza and which might be incorporated into the routine of the diagnostic laboratories of the hospital. Two samples of serum were collected from each of 59 of the patients, and these were tested both for neutralizing and for complement fixing antibodies.

METHODS

The neutralization test was performed by the method of Francis and Shope.² However the serum-virus mixtures were instilled in the nostrils of the mice with a capillary tube calibrated to deliver 0.05 cc. While it is doubtful whether this is much more accurate than Shope's method of immersing the nostrils in the fluid, it is more economical of serum and we were able to inject 4 mice with 0.2 cc. of the serum-virus mixture, which represents only 0.1 cc. of serum. The virus used was a 4 per cent saline suspension of freshly harvested mouse lungs taken from animals previously injected with the PR8 strain of influenza. The serum and virus were mixed and incubated at 37 C. for thirty minutes before injection. The mice were killed on the

sixth day and the presence and extent of lesions noted. This is the simplest and most economical protection test that has been devised. Its disadvantage is that samples taken from many patients during the acute phase of the disease, as indeed many random serums, will completely neutralize the virus. In such cases further tests with diluted serum are needed. Recent studies of the levels of neutralizing antibodies indicate that the actual titers have little diagnostic significance. The purposes of the present work seemed satisfied by the simpler method.

The complement fixation test was performed by the method described by Eaton and Rickard.³ It was found advantageous to modify the quantities of reagents. Serum dilutions were prepared in 0.2 cc. amounts, complement (2 units) and antigen in 0.2 cc. amounts, and no saline solution was added.

THE CAUSE OF THE EPIDEMIC

The results of the first neutralization test are shown graphically in chart 2 and suggest that the vaccinated group had a higher level of antibodies than the non-vaccinated at the time of onset. The results also show that at least many of the patients had influenza A, since many showed a distinct rise in specific antibodies. The remaining serums were examined in like manner and with very similar results. The same samples were also compared by means of the complement fixation test. In the unvaccinated group 22 patients were found to show a sharp rise in complement fixing antibodies, of 3 one or both serums were anticomplementary and of 3 no increase in complement fixing properties was detected. These may have been due to the fact that the first sample was collected rather late in the disease. Of 2 others the reaction was negative in both samples. Those serums which had completely protected mice in

Chart 2.—An influenza A neutralization test showing the extent of the involvement of the mouse lungs. Mice that died shortly after inoculation have been omitted. No distinction has been made between animals that died or were killed on the sixth day.

the first neutralization test were then reexamined, the amounts of virus previously employed being used but being mixed with serum diluted 1:8 and 1:32 with saline solution (chart 3). Of 8 patients so tested 6 were found to have increased antibody content in the convalescent samples, and the samples of the remaining 2 completely protected mice even in the 1:32 dilution.

These results have been summarized in table 1, where it may be observed that in 27 of the 31 control cases serologic evidence that the disease was due to influenza A was established by one or both tests. This represents 87 per cent of the cases in the group.

mainly on two observations: that vaccines elicit neutralizing antibodies and that persons with high antibody titers are in the main less susceptible to influenza than those with low titers. There is further encouragement in the successful vaccination of laboratory animals. It may well be that individuals with high antibody titers due to a natural encounter with virus may have superior and different resistance than those with similar titers the results of vaccination. Antibodies are only one measure of resistance. Tissue resistance may be much more important. The vaccine used in this study seems to be effective in eliciting antibodies. Yet it did not prevent influenza.

Against this failure to prevent influenza must be considered the evidence that the duration of the disease and pulmonary involvement seem to have been reduced by vaccination. If this can be proved to be consistently true, the advantages of vaccination might be much more conspicuous and important during a pandemic characterized by severe pulmonary complications and a high mortality rate.

We hope that our experience will induce other hospitals to undertake the etiologic diagnosis of influenza. The neutralization test is a simple and conclusive

THE KENNY TREATMENT OF INFANTILE PARALYSIS

A PRELIMINARY REPORT

WALLACE H. COLE, M.D.

ST. PAUL

AND

MILAND E. KNAPP, M.D.

MINNEAPOLIS

NOTE.—The following article is a preliminary report on the treatment of cases of acute infantile paralysis by the Kenny method. The authors state that this does not represent any original work on their part but is strictly a report of observation of the treatment as carried out by Miss Elizabeth Kenny and attempts only to present her ideas. Results of treatment of late cases were not included in this report because the period of observation was not sufficiently long. It is obvious that several years must elapse before a definite evaluation of the method can be made in terms of final results.

Continuation of the work for at least one additional year has been arranged for at the University of Minnesota Hospital and the Minneapolis General Hospital. It is hoped that a more complete report will be forthcoming at the expiration of that time.

It is, of course, recognized that spontaneous recovery may occur in cases of infantile paralysis without treatment of any kind. However, no accurate statistical studies of the incidence of spontaneous recovery have come to our attention.

Regardless of one's attitude toward the concept of infantile paralysis here presented, the fact remains that the currently accepted methods of treatment of the disease are far from satisfactory. The mere existence of The National Foundation for Infantile Paralysis, Incorporated, supported as it is by contributions from the entire nation, is prima facie evidence of the widespread recognition of the inadequacy of present methods of treatment.

For this reason the authors believe that the "Sister Kenny Method" should be given a fair trial and should be studied with open minds in the hope that improvement in the treatment of infantile paralysis might result.

There have been published to our knowledge four previous reports on the "Kenny method." These are:

I. The report of the Queensland commission, which condemns the method completely in every detail (*M. J. Australia* 1: [Jan. 29] 1938; summary of findings, *Brit. M. J.* 1:350 [Feb. 12] 1938).

II. The Carshalton report of the London County Council, which is summarized as follows (*Brit. M. J.* 2:852 [Oct. 22] 1938):

"1. We have seen no reason to admit Miss Kenny's claim that complete cure can be promised in any group of cases of poliomyelitis.

"2. We consider that the use of hydrotherapy in the form of hot and cold douches as practiced by Miss Kenny is of value.

"3. We consider that very early attempts to initiate voluntary movements and also early and frequent passive movements are harmless but of unproved value.

"4. We agree with Miss Kenny that under certain conditions, which we have specified, splints can be dispensed with in the treatment of the early stages of the disease. We do not approve, however, of her entire abolition of splints and surgical appliances in treatment. . . ."

"5. We consider that Miss Kenny has not really faced the issue of residual paralysis, for which we believe surgical appliances or surgical methods such as stabilizing operations offer the only eventful hope of amelioration."

From the Departments of Orthopedic Surgery and Physical Therapy, University of Minnesota Medical School.

This work has been supported in part by a grant from the National Foundation for Infantile Paralysis.

procedure well suited to the study of individual cases or small groups of cases. The complement fixation test is equally definite and the reactions are very sharp. It is much less expensive and time consuming if many samples are to be tested. Present indications are that complement fixation will prove to be invaluable in the diagnosis of various virus diseases. We have used it for a number of years in the diagnosis of lymphocytic choriomeningitis. In the present work considerable difficulty was experienced with anticomplementary reactions. When these were finally overcome, no serum remained from certain patients and these appear in table 1 as AC. Unfortunately antigen must be freshly prepared at present. If some means were found to preserve it and to supply it to diagnostic laboratories the complement fixation test could readily be introduced wherever Wassermann tests are now performed. Much would be gained by broadening the front on which influenza is now being observed and attacked.

Our results show that on occasion one of the tests may be negative when the other is positive. This does not occur often enough to detract seriously from the value of either.

CONCLUSIONS

An epidemic of influenza A occurred among a hospital employee population of 826 adults, half of whom had recently received the vaccine of Horsfall and Lennette. Vaccine was found to increase the neutralizing antibodies but not to prevent influenza. There is evidence that it may have reduced the incidence and favorably modified the severity of the disease.

III. The report of W. R. Forster and E. E. Price, in which the conclusions are briefly as follows (*M. J. Australia* 1:321 [Feb. 25] 1939):

"So far as this investigation goes it would appear that, excluding the quoted unsatisfactory cases, return of muscle power is comparable to that obtained by orthodox methods. Pain on movement and stiffness rapidly diminish and are never so marked as in the splinted cases. The tendency to deformity has given us less trouble than in cases with ill-fitting splints. . . . Correct splinting is an advantage for many cases of paralysis of the hand, foot, and abdomen, and may be regarded as an essential for home treatment and unruly cases.

"We are of the opinion that Miss Kenny has made a definite contribution to the treatment of poliomyelitis.

"1. She has provoked a critical and in several respects beneficial review of the treatment of poliomyelitis in general.

"2. She has drawn attention to the evils of improper splinting.

"3. She has contributed to the knowledge on the subject of stiffness and has emphasized the value, in this respect, of full and more frequent movements, beginning as early as the third week."

IV. The report to the Minister for Health of New South Wales by Kenneth W. Starr in May 1939. A few of his conclusions are:

"1. Sister Kenny has made valuable contributions (a) to our knowledge of the causes of stiffness in paralyzed muscles and of its prevention and (b) regarding the results, so commonly seen, of improper splinting.

"2. Sister Kenny has made no fresh contribution to the treatment of the disease as it affects the spinal cord.

"3. Sister Kenny's contributions deal with the problem of circulation in paralyzed muscles and should bring infantile paralysis into line with modern advances in the treatment of fractures and other orthopedic conditions in which muscle stiffness has now been largely eliminated.

"4. Sister Kenny has regimented various orthodox methods, and in some aspects improved on them. Her criticism of dilatory application of reeducation to paralyzed muscles in favor of routine splinting is justified.

"5. However, the criticism leveled by Sister Kenny at orthodox methods is certainly not entirely justified, as in certain valuable respects these methods are superior to her own.

"6. Her method cannot replace orthodox practices but its most favorable principles should be incorporated in units for the treatment of infantile paralysis."

The authors of the present article consider it significant that the tone of these reports becomes more favorable the earlier the cases come under treatment. The Queensland commission reported on late cases (treatment begun over six months after the onset of the disease). The Carshalton cases were called "early" if treatment was started within eight weeks. Forster and Price reported on cases coming under treatment "as early as the third week." Treatment in 52 of Starr's cases was begun between the fifth to the twelfth day after onset of the disease.

In a number of the cases included in the present report treatment was started as early as the second day of the disease. A case was considered "late" if treatment was started later than two weeks after the onset of the disease.

SUBCOMMITTEE OF THE AFTER-EFFECTS
COMMITTEE OF THE NATIONAL FOUNDATION
FOR INFANTILE PARALYSIS,
INC. M. E. KNAPP, M.D., Chairman
in the absence of WALLACE H. COLE,
M.D.

FRANK H. KRUSEN, M.D.

IRVINE MCQUARRIE, M.D.

For about six months, June to December 1940, we have observed and assisted in the treatment of infantile paralysis according to a method devised and developed in Australia by Sister Elizabeth Kenny. This treat-

ment has been carried on at the Minneapolis General Hospital and the University Hospital under the direct control and supervision of the orthopedic and physical therapy departments of the University of Minnesota. The actual treatment has been carried out by Miss Kenny herself with the assistance of the physical therapy and nursing staffs of these hospitals.

Miss Kenny has presented ideas which are new in the symptomatology and treatment of infantile paralysis. The technic is essentially a highly refined and detailed method of muscle reeducation. Results have been obtained in the cases of acute involvement which seem superior to those secured with therapeutic procedures previously generally accepted. One may not invariably agree with her explanations, but the results seem significant.

This preliminary report merely outlines the fundamental principles on which the therapy is based, presents briefly the technic and summarizes the progress of the patients thus far treated during the acute stage of the disease. Definite conclusions cannot yet be drawn. A continuation of the work may permit a more conclusive report in the future.

The Kenny treatment was developed in the Australian Bush through careful observations of the symptoms, signs and end results of infantile paralysis and its treatment. Miss Kenny had a keen, analytical mind unprejudiced by previous contact with theory or training in the prevalent conception of treatment of this disease. She was furthermore without knowledge of postmortem pathologic appearances. She was, in addition, thrown entirely on her own resources.

According to her concept, the cardinal symptoms of infantile paralysis are "muscle spasm," "muscle incoordination" and "mental alienation." This is opposed to the usual concept in which the cardinal symptom is conceived to be flaccid paralysis without muscle spasm or incoordination. The presence of spasm has been demonstrated in all cases of acute involvement observed in this study.

She believes that "muscle spasm" is a constant accompaniment of the muscular pain of acute anterior poliomyelitis and it may be the real and sole cause of the pain. It may also be a rational explanation for the rigidity of the neck and the back, which is usually dismissed with the term "meningeal irritation."

This spasm can be released effectively by the use of hot fomentations of the special type described later under "Treatment," and by this method the stage of muscle soreness can usually be shortened to three or four days. Sister Kenny contends that much of the permanent paralysis may be prevented, or at least reduced, by relief of this spasm as quickly and as completely as possible, for persistent muscle spasm may result in paralysis or muscle weakness in four ways:

1. The lesion which causes paralysis may so weaken a muscle that its fibers are irreversibly damaged by the added insult of prolonged muscle spasm which results eventually in the muscle becoming a hard, inelastic mass which has lost its essential power of contractility. This type of muscle in spite of all treatment will never recover and eventually results in the formation of contractures.
2. Muscle spasm in one group of muscles may result in overstretching of the opposing group so that a disuse atrophy or paralysis is produced in this

opposing muscle group although it is not directly affected by the disease. This apparent paralysis can be frequently cured within a few hours or days if adequate treatment is given to the muscles in spasm. 3. The severe pain resulting from attempts at motion when muscles are in active spasm may cause a subconscious alienation of the mental processes so that it becomes impossible to use these muscles consciously even months after the spasm has ceased. This must be treated by reeducation designed to reestablish "mental awareness" of the part after release of the spasm has been accomplished. 4. Pseudoparalysis may be produced by spasms so strong that other muscles are put at a mechanical disadvantage and therefore may appear paralyzed. Release of the spasm in these cases restores function.

Attempts of the patient to perform acts with weakened, paralyzed or painfully spastic muscles result in the substitution of other muscle groups so that a mental pathway is diverted to the wrong muscle. This results in "muscle incoordination." For instance, the patient may attempt to abduct the arm by contracting the pectoralis major, and this erroneous pathway may persist after the acute phase of the disease has passed and result in a wrong diagnosis of paralysis of the deltoid. Incoordination is treated by preventing all attempts to use painful and weak muscles except under careful supervision and direction and by restoration of coordination by proper muscle training. The latter is often a long and tedious procedure. Obviously in this treatment there is no place for "muscle testing" as usually performed—that is, attempting to determine the strength of each individual muscle—for this testing can definitely cause "incoordination" and may slow down the patient's recovery.

By "mental alienation" is meant the destruction or distortion of mental pathways so that a muscle is divorced from voluntary action. This may be a result of the fear of pain or it may be due to the disruption of conduction pathways or synapses by the disease itself through edema, hemorrhage or other pathologic process.

Mental alienation may be prevented to a greater or less degree by relief of pain and muscle spasm as quickly as possible. Treatment consists of very exact and persistent reeducation started at the earliest possible moment.

A treatment based on the foregoing principles obviously has no place for the use of splints or plaster of paris fixation. Miss Kenny lists the reasons for condemnation of the principles of immobilization as follows:

1. Immobilization prevents the treatment of the disease—that is, the symptoms of the disease—in the acute stage.
2. It prolongs the condition of muscle spasm and prevents its treatment.
3. It prevents the treatment for the restoration of coordination of muscle action, a serious error.
4. It promotes the condition of stiffness, which according to all reports prevents satisfactory treatment either for the symptoms that brought about the condition (muscle spasm) or the development of muscle power by reeducation, or the reawakening of impulse.
5. It interferes with nutrition of the skin, subcutaneous tissue and muscles.
6. It reduces circulation.

7. In any system of treatment it cannot prevent deformities. If introduced into the Kenny system it would not prevent deformity because it would prevent the treatment of the symptoms of the disease in the acute stage. It does not in the orthodox system prevent deformities, of which there is unfortunately abundant evidence.

8. It diminishes the volume of nerve impulses through the nervous system along the afferent and efferent paths.

9. It produces changes in the capsular ligaments and prevents their normal functioning.

10. It interferes with the normal function of the subconscious mind.

11. The synovial fluid tends to disappear and the joint to become dry.

12. It gives the patient an adverse psychologic outlook.

In this system the goal is coordinated, balanced function which is obtained by reestablishment of nerve pathways and mental processes, and minor importance is assigned to strength.

TREATMENT

A brief discussion of the usual treatment procedure may be instructive at this point. Sister Kenny states the purpose of the Kenny system as:

1. The treatment for the symptoms presenting themselves in the acute stage of the disease.
2. Maintenance in full vitality or maintenance of the healthy conditions of all tissues of the body, affected parts as well as unaffected, both somatic and visceral.
3. Reestablishment of normal nerve conduction paths and of normal function to the affected parts to the fullest extent possible.
4. Avoidance of all measures known to interfere with the attainment of these objectives.
5. Prevention of undesirable sequelae and complications.

The technic is roughly the following for a patient admitted within a day or two after the diagnosis has been made:

Especial attention is paid in the examination to the presence of muscle spasm, the location of pain and the extent and probable cause of apparent paralysis, and the patient is then placed on a firm mattress supported by bed boards. There is a foot board with the mattress sufficiently separated from it so that the heels or toes of the patient will not be resting against the mattress. This board is intended to maintain the normal standing reflexes arising from pressure of a hard surface on the soles of the feet and is in no way to be considered a splint.

The patient is placed in a position comparable to the normal standing position, with the arms at the side and the knees straight. No splints or casts are used. Hot fomentations are then applied to the affected muscles. These fomentations are made with boiling water from pieces of blanket cut to size which are passed twice through a very tight wringer and applied directly to the part. The joints are not covered and no cutaneous irritation occurs. These fomentations are renewed every two hours in most cases, every hour or half hour in cases of more serious involvement. Passive movements through the range of motion possible without pain are carried out several times a day. In addition an attempt is made to maintain awareness of the part by training once or twice a day as soon as muscle spasm is sufficiently reduced. As the pain is reduced the muscle training is increased to maintain normal nerve pathways and

restore those which are damaged. By the time the patient is ready to be released from the contagious ward the pain and spasm are usually gone and the reeducation has been well started. Periods of muscle training are carried on twice a day until the patient is normal or ready to be discharged from treatment.

The technic of reeducation of the muscles cannot be fully presented in this short paper. The principles are the establishment of awareness by pointing out the insertion of the affected muscle, then having the patient make a mental effort while the technician carries out the motion and finally having the patient make a physical effort. This procedure is repeated twice every day until the patient has useful function of the part, but only one to three active movements are ever allowed. Great care is taken to center all attention on the part being treated and to avoid overtiring the patient either physically or mentally. Meticulous attention is paid to body mechanics and exact muscle function. The details of this method of treatment cannot be learned quickly. The longer we have observed Miss Kenny's work the more we have realized that there is a reason for the two year period of training which her pupils receive in Australia.

The complete technic will no doubt be published in book form some time in the future.

REPORT OF CASES

To date 26 patients with acute anterior poliomyelitis have been treated under our observation by this method. Twenty received the Kenny treatment within two weeks after the onset of the disease. Eleven have already been discharged completely normal. The average hospital stay of these patients was thirty-six and two-tenths days. Of the remaining 9, 1 has paralysis of both legs which will probably be permanent. One was admitted only three weeks before the date of writing.

The other 7 are progressing satisfactorily, but it will take time to establish the extent of their final recovery.

In this series 11 of 20 patients are normal within two months after the onset. It is expected that at least 5 of the others will recover completely within a reasonably short period of time.

Of the 6 patients on whom the Kenny treatment was started from two weeks to two months after the onset of the disease, 2 have been discharged as completely well, 1 will probably have permanent paralysis of one arm and 2 are quite likely to have some degree of permanent paralysis. This would seem to indicate that early treatment may have some value in preventing the development of severe disabilities.

COMMENT

It is impossible at this time to attempt to evaluate end results or to do more than indicate impressions. Epidemics vary in their severity from year to year, and the percentage of the hospitalized patients who would have recovered completely under the usual therapy cannot be accurately estimated.

The patients observed were much more comfortable and cheerful during the acute stage than are those who are immobilized. Thus far, we have seen no contractures or deformities following this treatment. Even the most severely paralyzed patient has passively full range of motion in all his joints. Scoliosis or other spinal deformity has not developed in these cases. In

most of them there is more flexibility than there was before the onset of the disease. The patients are more comfortable and more cheerful, and it appears that the disability is less severe than would have been expected ordinarily. Certainly harm has not resulted to any of the observed patients under Miss Kenny's care from "abandonment of immobilization."

CROSS INFECTION WITH TYPE I PNEUMOCOCCUS

SYDNEY S. GELLIS, M.D.

AND

A. GRAEME MITCHELL, M.D.

CINCINNATI

That pneumococcic pneumonia is a contagious disease and that isolation procedures are necessary in the care of patients suffering from it have been emphasized by certain clinicians.¹ Smillie and Leeder² observed that 2 per cent of patients in contact with patients with pneumonia contracted pneumonia. In the report by Benjamin, Ruegsegger and Senior³ it was stated that 13 cases of pneumococcic pneumonia which were obviously due to cross infection occurred in the years 1936 and 1937 at the Cincinnati General Hospital and that during the following winter when isolation technic was enforced only two such instances of cross infection occurred.

Smillie⁴ has shown that type I pneumococcus is twenty times more prevalent in persons exposed to this strain than in the population at large. He stated, furthermore, that economic status and overcrowding play no role in increasing the number of positive contacts. The study of Benjamin, Ruegsegger and Senior,³ however, emphasized the influence of overcrowded hospital wards in the production of cross infection with pneumococci.

The following nine instances of cross infection with type I pneumococcus occurred in November and December of 1939 during a period of two weeks in the pediatric service of the Cincinnati General Hospital. All the children, with one exception, were between the ages of 2 and 3 years. It has been the practice to admit patients with pneumonia in this service to one large ward in which all patients are isolated and mask and gown technic is enforced. Because of the number of admissions, it is necessary at times to remove these patients during their convalescence to smaller wards in which isolation technic is not enforced.

Of the 9 patients 5 (1 to 5, inclusive) when admitted were suffering from bronchopneumonia and 1 (patient 6) from bronchitis and otitis media. The 3 remaining patients were not in the large ward at the time of admission of the other patients but were in small nearby wards. Patient 7 was suffering from pyelitis, patient 8 had nephritis and patient 9 was convalescing from a hernia operation.

Dr. Mitchell died June 1.

3. Benjamin, J. M., Ruegsegger, J. M., and Senior, F. A.: *Cross Infection of Pneumonia*, J. A. M. A. 112: 1127-1130 (May) 1933.

4. Smillie, W. G.: *Epidemiology of Lobar Pneumonia*, J. A. M. A. 101: 1281-1286 (Oct. 21) 1933.

Pneumococci isolated on admission by culture and mouse inoculation of material from the noses and throats of patients are recorded in the accompanying table, and it will be noted that in no instance was the type I pneumococcus present at that time. Patients 1 to 6 were given sulfapyridine therapy at the time of admission, the level of free sulfapyridine in the blood being maintained in all of them at 4 mg. per hundred cubic centimeters or higher. They responded well to the drug, and their temperatures returned to normal on the second to the third day after admission. In all 6 patients, however, after a normal temperature for from four to five days, fever suddenly developed and signs of further pulmonary infiltration were obtained on physical examination and confirmed by roentgenograms. With this secondary rise in temperature type I pneumococcus was obtained from the nose, throat, ear or blood as shown in the accompanying table. Patients 1 and 5 experienced

of temperature when type I pneumococcus was isolated. Patient 7, however, merely had an elevation of temperature which lasted twenty-four hours and subsided without treatment.

Healthy carriers were apparently not the cause of these infections, since inoculation of mice with cultures of material from the nose and throat of all nurses, physicians, orderlies and maids working in the wards failed to recover type I pneumococcus.

During convalescence of the 9 patients cultures of material from the nose and throat were repeatedly taken. Fourteen days after the initial isolation of type I pneumococcus from these patients cultures of material from the nose and throat of 4 were negative for the organism, and by forty-two days those from all patients were negative. Convalescence in every case was uneventful.

The nine instances of cross infection with type I pneumococcus cited emphasize the necessity for strict

Cross Infection with Type I Pneumococcus: Clinical Summary

Case	Diagnosis on Admission	Culture of Material from Nose and Throat on Admission	Chemotherapy	Day After Admission on Which Temperature Was Normal	Day on Which Treatment Was Discontinued	Day on Which Secondary Rise in Temperature Occurred and Type I Pneumococcus Was Found	Source of Type I Pneumococcus	Respiratory Involvement with Type I Pneumococcus Infection
1	Bronchopneumonia	Pneumococcus type XIX	Sulfapyridine	Second	Ninth	Sixth	Nose and throat	Pneumonia, lower lobe of left lung; bilateral bronchopneumonia
2	Bilateral bronchopneumonia	Pneumococcus type VI	Sulfapyridine	Second	Fifth	Seventh	Nose, throat and blood	Bilateral bronchopneumonia with spread
3	Bronchopneumonia, left lung	No pneumococci	Sulfapyridine	Second	Fourth	Ninth	Nose and throat	Bronchopneumonia with spread
4	Bilateral bronchopneumonia	Pneumococcus type VI	Sulfapyridine	Second	Eighth	Ninth	Nose and throat	Bronchopneumonia with spread
5	Bronchopneumonia, right lung	Pneumococcus types XIII and XVI	Sulfapyridine	Third	Seventh	Seventh	Nose, throat and blood	Bronchopneumonia in right lung, with spread
6	Bronchitis, otitis media	No pneumococci	Sulfapyridine	Second	Sixth	Seventh	Nose, throat and blood	Pneumonia, lower lobe of left lung
7	Pyelitis	Sulfanilamide	Ninth	Eleventh	Twelfth	Nose and throat	Pharyngitis
8	Nephritis	Twenty-eighth	Nose, throat and blood	Bilateral bronchopneumonia
9	Hernioplasty	Twentieth	Nose and throat	Pneumonia, lower lobe of left lung

the secondary rise in temperature while still receiving sulfapyridine. This rise occurred one day after the drug had been discontinued in patients 4 and 6, while in patient 2 it occurred after two days. In patient 3 the rise did not occur until five days after chemotherapy was discontinued.

Patients 7, 8 and 9 were exposed to infection with type I pneumococcus when patients 1 to 6 were removed during their convalescence to the smaller wards. Patient 7, who was suffering from pyelitis, had been in the ward twelve days prior to the rise in temperature which accompanied his infection with type I pneumococcus. Similarly, patient 8, who was suffering from nephritis, had been in the ward twenty-eight days, and patient 9 had been in the ward for twenty days after an operation for hernia. These 3 patients showed no evidence of infection of the respiratory tract on admission, and cultures of material from the nose and throat which yielded type I pneumococcus were taken because of the suspicion that the infection was spreading in the ward.

Roentgenograms of all patients, with the exception of patient 7, showed either pulmonary infiltration or increase in previous infiltration at the time of the rise

isolation technic in the care of patients with pneumococcal pneumonia. From our experience and from the results of previous studies it would appear that precautions regarding isolation should not be terminated when the patient is apparently convalescent but should be continued until his discharge from the hospital or until such time as repeated cultures of material from the nose and throat are negative for pneumococci.

First Laboratory of Experimental Psychology.—Wilhelm Wundt (1832-1920), the famous professor of physiology, while at Zurich was interested in reflex actions and other neural mechanisms, into which he attempted to translate a large proportion of human behavior. His isotonic curves representing muscle tissue under constant excitation have been the starting point for many research problems throughout the years. His well known classic, *Elements of Physiological Psychology*, has been extended through six editions. He established in 1876 the first laboratory of experimental psychology, which became the model for many later ones. The second laboratory of this kind was organized in 1883 by G. Stanley Hall (1849-1924) at Johns Hopkins University.—Lewis, Nolan D. C.: *A Short History of Psychiatric Achievement*, New York, W. W. Norton & Co., Inc., 1941.

THE USE OF SURFACE ANESTHESIA IN THE TREATMENT OF PAINFUL MOTION

HANS KRAUS, M.D.

NEW YORK

This paper describes a method of treatment for impaired function when pain is the factor responsible for the loss of motion or power. The treatment is the application of a surface anesthetic (ethyl chloride spray) combined with active motion.

DEVELOPMENT OF THE TREATMENT

In 1933 a gymnastic teacher—Heinz Kowalsky—suggested that treatment of sprains and pulled muscles by immobilization was not satisfactory to active sportsmen. He said that professional sportsmen had found by experience that immediate active motion after any such injury provided the quickest cure. He further told me that he usually advised his pupils to rub their injured joints with alcohol and expose them to live steam for a time. Numbness of the joint was said to result, and active motion was started as soon as this numbness set in. The result of this treatment was said to be satisfactory and superior to treatment by immobilization.

I tried the treatment in a few cases of minor sprain with success, but in cases of severe involvement when the patient lacked energy to undergo this prolonged and unpleasant procedure it failed. I then tried other readily evaporating liquids and finally adopted ethyl chloride, which has been used with success. At first only sprains were treated; later, acute muscular spasms due to conditions such as lumbago and acute bursitis of the shoulder as well as muscular spasm accompanying various chronic conditions, such as sciatica, low back pain and pain recurring after old injuries.

The use of active motion is an essential part of the treatment. With more experience in the proper use of active motion, better results were obtained. The experience thus gained has been published (1935 to 1938) in various papers.¹ Other authors (Creer,² Cozen and Hollombe³) published their experiences with ethyl chloride spray in 1939 and 1940.

INDICATIONS FOR USE

Experiences recently gained in the fracture division of the Presbyterian Hospital have confirmed previous observations. Though further research will be necessary for final conclusions, the following groups of cases are considered suitable for treatment by surface anesthesia and active motion, if major disturbance of the normal anatomy, such as fractures or a complete tearing of ligaments, muscles or tendons of the affected region are absent: (1) sprains of all joints; (2) acute muscular spasm due to lumbago, acute bursitis of the shoulder, pulled muscles, and so on, and (3) chronic muscular spasm due to "low back pain," sciatica, chronic osteoarthritis, shoulder spasm and the like.

3. Cozen, Lewis, and Hollombe, B. S.: *Ethyl Chloride Spray for Sprained Ankles*, Surgery 8: 468 (Sept.) 1940.

The common symptom treated in these conditions is limitation of motion through pain and subsequent spasm. Major changes in anatomy, such as fractures or tears of soft parts, are treated by the usual surgical methods. Whenever treatment with ethyl chloride spray gives a negative result, it will be necessary to look for major changes in the anatomy. Thus this technic may be used as a means of evaluating diagnosis in cases of impaired function.

TECHNIC

The painful region must be determined through active motion. The direction in which the motion is impaired is first determined. Then ethyl chloride is sprayed on this area of skin. The patient then starts careful active motion of the part involved, in the direction in which the motion has been painful and limited. As the patient carefully increases the movement, new painful areas—which up to this point have been hidden through blocked motion—will develop. Those areas again have to be sprayed and active motion continued.

These treatments last from ten to thirty minutes and should be performed carefully and well within the limits of pain. Immediately after the treatment, camphor liniment should be applied to the skin, to avoid frostbite.

Immediate normal use of the affected part can be allowed in a majority of cases, but excessive strain and sudden movement should be prohibited. Patients with more severe disorders should be given a rest, but all patients should be advised to continue the active movements taught them—from twice a day to once every hour—for approximately five minutes. While a single treatment will be sufficient in cases of minor involvement, patients with more severe involvement will have to be treated several times: the first week, daily—later, every other day.

An effective treatment, however, should not call for the anesthetic after the second week, whereas active motion will have to continue until normal muscular power is restored.

Immobilization after treatment is contrary to the basic principle and should, therefore, never be combined with it.

RISKS IN THIS TREATMENT

Excessive use of ethyl chloride spray may result in frostbite of the skin. To prevent this, camphor liniment or other counterirritants should always be used.

I have used a spray composed of ethyl chloride with camphor liniment and compounds of ethyl chloride with various oils with good success. These oils, mixed with the ethyl chloride and thus used in proportion, provide an immediate antidote against irritation of the skin.

A mixture of ether, alcohol, acetone (of each 100 parts) and camphor liniment (20 parts) applied after the spraying, has been found helpful in aiding the effect of ethyl chloride and in acting as a counterirritant at the same time.

Active motion, though absolutely necessary, should never be used brusquely or abruptly, in order to avoid injuries to the spastic muscles, which would obviate the effect of the exercise.

As previously emphasized, normal anatomy must be present if this treatment is to be used effectively. Whenever this point is neglected, treatment with ethyl chloride either has no effect or, as with any other treatment when wrongly applied, will cause damage.

RESULTS

In acute attacks the effect of the treatment is amazing. Patients who have been disabled by acute sprains or acute muscular spasm often regain the full use of the affected parts immediately. The pain frequently does not recur in cases of minor involvement and rarely recurs in full intensity in those of more serious involvement. Two to four treatments usually suffice to bring about, even in more serious cases, a minimum degree of discomfort. Thus, in all cases the period of disability is reduced drastically. Atrophy of the muscles involved does not develop to the same degree as when immobilization is employed. Swelling is more readily absorbed. Patients treated by this method are less apt to sustain the same injury again than those treated by immobilization. The same holds true for chronic and "rheumatic" conditions, although a longer period of treatment is usually required in those cases.

As a means of aiding in diagnosis and in the evaluation of roentgenograms, this treatment is of great value. Further analysis and experience will be needed to establish general rules.

As compared with the injection of procaine hydrochloride into the muscles and ligaments (Leriche⁴), this method shows the following advantages:

1. Application is simpler.
2. Repeated application is possible, with less difficulty and risk.
3. Large areas can be controlled which otherwise would call for the use of vast quantities of procaine hydrochloride.
4. It does not work when fractures or tears are present; thus it is less dangerous and more selective.
5. It is more advantageous in its use as a diagnostic means, being more selective.
6. There is less risk of a local after-effect and no general after-effect such as is sometimes seen after the administration of procaine hydrochloride.
7. There is no danger of infection.

THEORY

Payr⁵ described the "chain effect of painful muscle spasm." He described how pain, originating in one portion of the sensory motor chain, leads to reflex muscular spasm and locking of joints. This chain consists of the following elements: sensory nerve, nerve center, motoric nerve, muscle and sensory nerve. Pain originating in the course of this chain leads to muscular spasm. The spasm is in itself painful and leads to more spasm. Elimination of pain at any point of the chain results in the breaking of the chain and therefore in relaxation of the muscular spasm. This may be achieved directly by the injection of an anesthetic into the muscle, joint, ligament, sensory nerve or spinal cord.

If the pain-free interval is used to restore the muscle to normal function, the spasm does not recur or recurs with much less intensity. Empirically, on the basis of this chain, cutaneous anesthesia similarly relieves the deep-seated pain in muscular spasm.

I have no explanation to offer as to how this deep effect of surface anesthesia works. It seems to be a fact, but the underlying physiologic explanation presents an interesting field for exploration. It must be definitely understood that in no case will the ethyl chloride alone, without active motion, achieve good results.

The considerable shortening of the period of treatment and the early rehabilitation with restoration of normal function make it desirable that this treatment should find general application. This is true especially in athletic injuries and injuries occurring to laborers and to those in the military service.

Clinical Notes, Suggestions and New Instruments

VENTRICULAR FIBRILLATION CAUSING SUDDEN DEATH OF A PATIENT WITH DISEASE OF THE LEFT CORONARY ARTERY

IVAN THOMPSON, M.D., OGDEN, UTAH

In recent months there have been several articles published dealing with various phases of the terminal cardiac mechanism in patients suffering from disease of the coronary arteries. The presumption is that sudden, unexpected death both of patients with angina pectoris and of those with coronary occlusion is generally due to fibrillation of the ventricles. There is evidence, however, that in at least some such cases the terminal cardiac mechanism is ventricular standstill due to overwhelming, sudden stimulation of the vagus resulting in paralysis of the pacemaker. There have been but very few electrocardiograms recorded at the time of sudden death of patients with these conditions. Therefore but little direct evidence is available as to the exact terminal cardiac mechanism.

Fig. 1.—Standard leads: The PR interval is at the upper limit of normal, measuring 0.2 second, while the QRS interval is approximately 0.08 second. Lead 1 shows two premature beats apparently arising in the right ventricle, while in lead 2 a short paroxysm of ventricular tachycardia is seen. The ventricular rate during this paroxysm is variable, and the complexes are of many different shapes. The three leads taken as a whole show considerable left axis deviation with small Q waves in lead 1 and prominent Q waves in lead 2.

In a review of the literature on this subject in 1939, Smith¹ found 4 published instances of electrocardiograms showing ventricular fibrillations causing sudden, unexpected death. To the list he added a fifth case, this being the first recorded of a person who had had an acute coronary thrombosis just a few hours previously.

In November 1940 Goodrich² reported the unusual experience of observing in one afternoon the terminal cardiac mechanism in 2 instances of sudden death from disease of the coronary arteries. In 1 case cardiac standstill developed after a period of ventricular tachycardia; in the second ventricular fibrillation occurred during the period of terminal cardiac activity. Goodrich pointed out that the first patient, dying after cardiac standstill, offered further support to the contention of Grieco and Schwartz, who in 1938 first demonstrated that ventricular standstill might be the cause of death after acute coronary thrombosis. Goodrich's second case, in which the terminal car-

VENTRICULAR FIBRILLATION—THOMPSON

Jour. A. M. A.
JUNE 7, 1941

diac mechanism was ventricular fibrillation, was the sixth proved instance of this type to be reported.

My purpose in this report is to add the seventh instance of proved ventricular fibrillation occurring as the terminal cardiac action in a case of disease of a coronary artery. There have been numerous patients who have recovered from occlusion of a coronary artery and then months or years later have died suddenly, unexpectedly and without warning. The case about to be reported was such. As chance would have it, an electrocardiograph was connected to the patient at the moment death so suddenly and unexpectedly occurred.

REPORT OF CASE

F. W. A., a white man aged 66, for many years an employee of a railroad in the commissary department, had been seen three or four times a year over a period of thirteen years for periodic examinations, as insisted on by his employer. The reason for

On the morning of the seventh day after leaving the hospital, while still in bed, he was seized with a severe substernal pain which radiated to both shoulders and arms and which was accompanied by extreme shock. He was hospitalized immediately. The picture at the time and the subsequent course were typical of coronary occlusion; however, no electrocardiograms were obtained. He gradually improved, finally being discharged from the hospital eleven weeks later. On discharge from the hospital he was entirely free from pain, was in good spirits and was ambulatory. He remained quietly at home for the next six weeks, although he was able to take short walks each day. Seventeen weeks after the coronary accident he went to California for a visit but finding himself dissatisfied there returned home after about three weeks. After returning he complained of some mild substernal pain on moderate exertion and became apprehensive and depressed. He was easily fatigued and also experienced palpitation at times.

Because of these symptoms I was asked to examine the patient and obtain an electrocardiogram. I called at the patient's home about noon on Feb. 2, 1940, which was about twenty-three weeks after the coronary accident. He met me at the door fully dressed and apparently in the best of spirits. We conversed for about fifteen minutes while the electrocardiograph was being arranged and the electrodes connected. The patient remarked during this preparation that he had felt considerably better for the past several days. From all outward indications he seemed to be perfectly well. The three standard leads were then taken. While lead 2 was being recorded the string in the view box was noted to be acting wildly, but after a relatively brief period it settled down and leads 2 and 3 were completed without incident.

It took approximately two minutes to change the connection in preparation for the chest lead, and during this interval the patient related an interesting experience he had had. When the recording of the chest lead was started the string again was noted to be wild in its action. The radial pulse was not readily palpable. On my placing a stethoscope over the patient's precordium the wild action of the string was readily accounted for. When asked if he was feeling all right he stated that except for a sense of palpitation he felt fine. The record was left running for a total of two minutes and twelve seconds. Near the end of the period the patient rose halfway up in bed as a result of a convulsive movement and then fell back on the pillow obviously dead. He did give one or two slight gasps afterward, but there were no other movements of any kind. Artificial respiration, stimulants and intracardial injections of epinephrine were given, with no response whatever.

The convulsive movement is recorded near the end of the lead 4 strip by the string wavering over the film. Whether or not the last heart beat is recorded is doubtful. The electrocardiograph was turned off four fifths of a second after the last deflection of the string; however, in the confusion resulting from the unusual turn of events, one of the electrodes may have been unwittingly disconnected. It seems apparent that the string should have been photographed on the remaining strip as a straight line if no cardiac action was occurring rather than being abruptly terminated as the tracing shows. This point is of relatively small importance, however.

An autopsy was performed by Dr. G. W. Schelm. The cardiac changes alone were of importance. The heart weighed 445 Gm. There were multiple areas of healed infarction over the lateral and posterior surfaces of the left ventricle. The coronary vessels were dissected out completely. The right vessel and its branches were found patent throughout, and the wall of the vessel showed only an occasional patch of atherosclerosis. The left coronary artery was tortuous and greatly thickened. The lumen was completely or nearly completely obliterated in several places. The vessel had been completely occluded 2.5 cm. from its ostium, and recanalization through the obstruction had subsequently occurred. There was no evidence of a fresh thrombosis.

COMMENT

As shown by autopsy, this patient had had an old coronary occlusion with healed myocardial infarction which apparently had occurred six months before. He had recovered sufficiently from this so that he was ambulatory, although his condition

of the rate is approximately 215 per minute but toward the end and before the complexes become entirely irregular the rate is approximately 300 per minute.

these frequent check-ups was mild hypertension; the blood pressure gradually increased over the thirteen year period to a maximum of about 180 systolic and 110 diastolic. The patient had always been of the extremely nervous type, had worried a great deal and had been especially apprehensive over the fact that his company regarded his hypertension seriously enough to require a check-up every three months, although this was a policy of the company with all such employees. His health remained generally good until July 23, 1939, when he suffered a cerebral accident while on duty at a company hotel. This paralysis of the right arm and leg together with some aphasia. His blood pressure the day following the accident was 210 systolic and 130 diastolic. He was hospitalized for two weeks, during which time the partial paralysis promptly cleared up; when he was discharged from the hospital the only remaining evidence of the cerebral accident was weakness of the right arm. His blood pressure on discharge was 150 systolic and 80 diastolic.

was such that he was not able to return to work. His cardiac symptoms for the few weeks preceding his death were those of coronary insufficiency; however, the mental symptoms of nervousness, fear and depression dominated the clinical picture. Figure 1 shows the standard leads, which, although not of normal pattern, failed to reveal the imminent catastrophe. It will be noted in lead 2 that ventricular tachycardia was established for a short time but immediately reverted to normal sinus rhythm. It is possible that the attacks of palpitation complained of were due to the occurrence of ventricular tachycardia.

It is unfortunate that the lead 4 strip was not started a few seconds before, at which time it might have recorded the transition from the normal sinus rhythm to the fatal arrhythmia. Lead 4 is one continuous strip taken over an interval of two minutes and twelve seconds. It will be noted that during most of this period tachycardia of ventricular origin was present. This finally changed into ventricular fibrillation, which was the terminal cardiac mechanism.

SUMMARY

In the case here reported, there were present clinical features and postmortem evidence of advanced disease of the left coronary artery, thrombosis and healed infarction. Death occurred suddenly and unexpectedly because of the establishment of ventricular fibrillation. This is the seventh such case to be reported in the literature. It is the first of its particular kind recorded.

RECOMMENDATIONS FOR A VENEREAL DISEASE CONTROL PROGRAM

IN STATE AND LOCAL HEALTH DEPARTMENTS

R. A. VONDERLEHR, M.D., ASSISTANT SURGEON GENERAL, U. S. P. H. S., WASHINGTON, D. C., CHAIRMAN; HERMAN N. BUNDESEN, M.D., CHICAGO; JOSEPH EARLE MOORE, M.D., BALTIMORE; N. A. NELSON, M.D., BOSTON; P. S. PELOUZE, M.D., PHILADELPHIA; WILLIAM F. SNOW, M.D., NEW YORK; JOHN H. STOKES, M.D., PHILADELPHIA; U. J. WILE, M.D., ANN ARBOR, MICH., AND LIDA J. USILTON, M.A., STATISTICIAN, U. S. P. H. S., WASHINGTON, D. C.

More than five years ago an Advisory Committee to the U. S. Public Health Service described plans for venereal disease control work in health departments throughout the United States.¹ Since that time a broad program of federal aid has been developed to supplement state and local facilities for the control of the venereal diseases. In the ensuing years, material progress has been made in the control of syphilis. Some advance has been made against gonorrhea, but it seems probable that the next few years will see much greater progress against this disease when full utilization is made of modern methods for its diagnosis and treatment. There has also been further accumulation of knowledge of the public health control of the venereal diseases. It therefore seems desirable at this time for the committee to reconsider former recommendations and to revise plans wherever such revisions seem to make possible a more efficient program.

The report of the committee will be divided into two parts—the first will make only broad recommendations pertaining to the control of the venereal diseases; the second (in process of publication) will describe those

Report of an Advisory Committee to the United States Public Health Service, Revised April 15, 1941.

1. Vonderlehr, R. A., and others: Venereal Disease Control Program in State and Local Health Departments. Report of an Advisory Committee to the U. S. Public Health Service, *Ven. Dis. Inform.* 17:1-16 (Jan.) 1936.

detailed measures which the committee considers to be the most desirable and effective parts of a good program. The general recommendations are made here.

ORGANIZATION AND ADMINISTRATION

Venereal disease control work should be the function of a separate division in the state or large municipal health department. Where this is impracticable, the work should be the function of a subdivision with a high degree of autonomy in the division of communicable disease control.

In either case, the program should be directed by a venereal disease control officer who has been adequately trained in the administrative aspects of this work, who gives his entire professional time to the duties of his office and who otherwise is qualified as recommended by the Surgeon General of the Public Health Service after conference with the state and territorial health officers.² This health officer should be supported by an adequate clerical staff. In health departments serving large numbers of people it may be necessary to provide additional administrative and technical personnel to assist the venereal disease control officer.

The duties of the venereal disease control officer and his staff are (1) a definition of the aims, purposes and policies of the venereal disease control program; (2) the collection and analysis of morbidity data; (3) the establishment of effective cooperation with physicians in private practice; (4) the development of cordial relations not only with the public but with special scientific groups; (5) administrative consultation to other units within the health department such as the Laboratory Section, the Maternal and Child Health Section and the Industrial Hygiene Section; (6) the organization and supervision of venereal disease clinics; (7) the organization and supervision of epidemiologic and follow-up services for clinics and private physicians, and (8) study and control of the efficiency of venereal disease clinics in terms of contact tracing, efficacious treatment and case holding, utilizing for the purpose a mechanical statistical system or some other equally effective plan.

In the organization and administration of the venereal disease control program the advice and assistance of a state or local committee should be sought. This committee should be composed of members of the medical profession and scientific and technical personnel from interested related professions, as well as representatives of business and social groups.

MORBIDITY REPORTS

The venereal disease control officer should be given the responsibility for the collection of adequate morbidity reports. The morbidity report form should contain as a minimum the following items:

1. Date of report.
2. Name or initials or identification number of patient.
3. Address of patient.
4. Age or birth date, color and sex of patient.
5. Duration of infection.
6. Diagnostic classification:

Syphilis—

Acquired: Primary. Secondary.
Early latent (less than four years' duration).
Late latent (four or more years' duration).
Congenital (specify manifestations).

Gonorrhea—

Genital. Eye. Other.

Chancroid—

Granuloma inguinale.

Venereal lymphogranuloma.

2. Proc. Conference State and Territorial Health Officers, 1939, U. S. Public Health Service.

7. Laboratory confirmation of diagnosis (dark-field, blood, smear, culture, Frei test, or intracutaneous test for chancroid, reported as positive, doubtful, negative or not done).

8. Information concerning amount of previous treatment.

9. Statement as to whether or not patient with syphilis is pregnant at time of beginning treatment (if pregnant, months pregnancy has advanced or the expected date of confinement).

In those areas in which facilities exist to provide the treatment source with contact tracing and case holding service, stubs should be included on the morbidity report form for requesting this service. Items on such stubs should be as follows:

I. Discontinued Treatment Notice.—1. Patient identification (name, address, age, color, sex). 2. Disease and date of infection. 3. Amount of treatment before lapse. 4. Date of last treatment. 5. Date and result of last laboratory report. 6. Identification of treatment source and signature of physician or administrative officer.

II. Section on the morbidity report form for epidemiologic investigation providing space for the names, addresses, relationship, and age of all familial or extrafamilial contacts within the preceding sixty days. When these data are not available for extrafamilial contacts, space should be available on the form for a brief description of each such contact.

The state health department should provide, distribute and collect morbidity reports without expense to the physician and with a minimum demand on his time. If possible, use should be made of these reports to establish incidence and prevalence data for the venereal diseases and to indicate the trend of these infections. The physician in private practice who submits the reports should be advised of the observations that are made as a result of the study of these forms.

LABORATORY SERVICE

Adequate and universally available laboratory service for dark field examinations and serologic tests for syphilis and for microscopic and cultural examinations for the gonococcus are essential in the control of these diseases. This laboratory service should be available without charge on the request of any licensed physician without the requirement that the patient from whom the specimen is taken be certified as to indigency.

There should be at least one state laboratory which may be supported by as many branch and local laboratories as the demand for service may require. Under certain circumstances, approved private laboratories may be subsidized instead of organizing new branch laboratories. When such private laboratories are utilized, the cost per test of performing the laboratory work should not exceed the prorated cost in the central state laboratory.

The recommendations of the Committee on Evaluation of Serodiagnostic Tests for Syphilis in the United States should be accepted as standard for the collection and transportation of specimens, the efficiency of performance of serologic tests for syphilis and the method of reporting results. A satisfactory plan for the intra-state study of efficiency of performance of serologic tests for syphilis was approved by the Committee on Evaluation of Serodiagnostic Tests for Syphilis during the Assembly of Laboratory Directors and Serologists, held at Hot Springs National Park, Ark., in the autumn of 1938.³

Every public venereal disease clinic should be equipped for direct dark field examination for the detection of *Spirochaeta pallida* as rapidly as clinic physicians or technicians can be trained in the recog-

nition of this organism. The indirect method of dark field examination is urgently needed in many parts of the country as an aid in the diagnosis of seronegative primary syphilis, but this method has not as yet been demonstrated on an extensive scale to be an effective, practical method for the detection of *Spirochaeta pallida*. Further intensive study of the indirect method is necessary not only because of its potential value to general practitioners in rural areas but also because of the dearth of physicians and technicians trained and experienced in direct dark field technic.

Every health department laboratory and clinic should be equipped for the examination of smears to detect the gonococcus. Only the Gram stain or a modification which has been approved by some competent authority in bacteriology should be used in making this microscopic examination.

Improved technics for the cultivation of the gonococcus make it important for all health department laboratories to provide this service unless some empiric chemotherapeutic scheme for the control of gonorrhea can be applied after symptomatic cure has been attained. Such cultures should also be made available in all venereal disease clinics as rapidly as circumstances will permit.

TREATMENT FACILITIES

Eligibility of Patients for Medical Care by the Health Department.—Clinic service without cost should be provided for (a) the diagnosis and emergency treatment of all persons who apply; (b) all patients referred by private physicians either for continued treatment or for consultation, and (c) all patients unable to pay for private medical care. Since the venereal diseases constitute a nationwide problem, it is essential that non-resident and transient persons be as eligible for clinic service in the community as are residents of that community. The integration of the work of various public and private agencies for the treatment of the venereal diseases is a major problem for the venereal disease control officer. To win the enthusiastic cooperation and acceptance of modern standards for the control of the venereal diseases from hospitals and groups who feel no need for public funds and have little desire to accept public guidance should be as much an objective of the campaign as to purchase such cooperation from clinics and groups eager to supply it in exchange for subventionary funds for equipment and personnel.

Clinics.—Clinics should be located so as to be easy of access and of maximum convenience to the population of the areas which they serve. The number of clinic sessions should be such as to meet the needs of the area without overcrowding or unreasonable delay. Night sessions should be held in sufficient number and at such hours as may be necessary to prevent economic loss to employed patients.

Clinics should be held in clean, well lighted and well ventilated rooms, so located and arranged as to offer privacy but not to imply isolation or segregation. The physical arrangements should be such as to insure complete privacy in history taking, physical examination and the administration of treatment. Adequate waiting rooms should be provided together with the necessary toilet facilities.

The equipment of the venereal disease clinic may be relatively simple if it is part of a polyclinic. If it is an *ad hoc* clinic the minimum diagnostic equipment should include an ordinary and a dark field microscope, blood pressure apparatus, stethoscope, ophthalmoscope,

3. The Serodiagnosis of Syphilis, supp. 9 to Ven. Dis. Inform., U. S. Public Health Service, 1939, p. 87.

vaginal speculum and the necessary stains and reagents for the examination of microscopic smears and of the urine.

The clinical records for male and female patients with gonorrhea recommended by the American Neisserian Medical Society in cooperation with the Public Health Service have this Advisory Committee's endorsement. In addition, this committee has prepared for use in clinics standard record forms for patients with syphilis.

The Subcommittee on Venereal Diseases of the Committee on Chemotherapeutics and Allied Subjects of the National Research Council has recommended for use of the Medical Corps of the Army and Navy and of the Public Health Service a standard nomenclature for syphilis, and it is urged that this nomenclature be adopted by all clinics cooperating with state and local health departments.

The minimum clinic personnel should consist of a qualified physician who will serve as director and clinician in charge, a qualified nurse to assist the physician in the technical aspects of clinic operation and a clerk to keep the clinic records and prepare statistical reports pertaining thereto. In larger clinics additional clinicians, nurses and clerks should be employed to insure effective work as the attendance increases. To this fixed intramural personnel there should be added an adequate field follow-up service, as discussed in the section on case finding and case holding. The medical and nursing personnel in the clinic and the follow-up personnel should possess the qualifications described by the members of the Conference of State and Territorial Health Officers.²

Standard schemes of treatment should be adopted by clinics for all patients with early and latent syphilis and syphilis in pregnancy, and gonorrhea in male and female patients. These standards have been described by the Cooperative Clinical Group⁴ and by the American Neisserian Medical Society⁵ working in cooperation with the Public Health Service and by the Subcommittee on Venereal Diseases of the Committee on Chemotherapeutics and Allied Subjects of the National Research Council. Such schemes should be strictly adhered to unless untoward reactions develop.

In rural areas, facilities for the clinical management of the venereal diseases may be provided by the use of (a) mobile clinics, (b) traveling treatment teams and (c) subsidization of private physicians. The mobile treatment unit has been demonstrated to be effective and economical and to provide adequately for the clinical management of the venereal diseases in rural communities in which facilities for stationary clinics do not exist. It permits at a relatively slight increase in cost the more intensive utilization of the services of the minimal clinic team—clinician, nurse and clerk. Both the mobile clinic and the traveling treatment team render the greatest service in those areas having a well organized health department and should operate under the administrative control of the local health officer. It is desirable that other public health measures necessary for the control of the preventable diseases in general be provided both in the mobile clinic and by the traveling treatment team.

E., and others: The Treatment of Latent Syphilis, *ibid.* 13: 317-331 (Aug. 20), 351-364 (Sept. 20), 371-379 (Oct. 20) 389-401 (Nov. 20), 407-412 (Dec. 20) 1932; 14: 1-12 (Jan.) 1933. Cole, H. N., and others: Syphilis in Pregnancy, *ibid.* 15: 83-107 (March) 1934.

5. Recommendations for a Gonorrhea Control Program: Report of an Advisory Committee to the United States Public Health Service, *Ven. Dis. Inform.* 19: 1-5 (Jan.) 1938.

To determine the efficiency of clinics under the supervision of or cooperating with health departments, it is necessary that a system for appraisal of clinic work be established. This system should account for the stage of infection when each patient seeks treatment, the amount of treatment received, the regularity of administration of treatment and the temporary or permanent lapse of the patient from the treatment schedule. In addition, the system should account for the duration of pregnancy when treatment is begun in pregnant women and for the thoroughness of treatment during pregnancy. The effectiveness of the case finding program in a given clinic should also be measured by accounting for the number of alleged contacts and the number of such contacts brought in for examination and treatment if necessary. The mechanical system of reporting morbidity, progress of treatment and control of the venereal diseases is believed to be the most effective system for the appraisal of clinic work, and it accounts likewise for the reporting of morbidity in the clinics in which it is operated.

Hospitalization should be provided at the request of the director of the venereal disease clinic for (a) open early syphilis in recalcitrant persons, (b) lumbar puncture, postlumbar puncture reactions, (c) fever therapy for neurosyphilis, (d) acute congenital syphilis in infants, (e) acute interstitial keratitis when local treatment is necessary, (f) various forms of late visceral syphilis, (g) acute gonococcal pelvic inflammatory disease, (h) gonococcal vulvovaginitis in children coming from homes where there are other girls and where home conditions are poor, (i) gonococcal ophthalmia in any age group, (j) gonococcal arthritis and (k) the severe acute complications of gonococcal infection such as epididymitis, prostatic abscess and pelvic abscess.

Distribution of Drugs.—At least two of the common arsenical preparations (one to be an arsenoxide) and at least one generally accepted bismuth preparation should be distributed without cost to physicians and all other medical agencies authorized by law to administer such drugs in the treatment of syphilis. At this time, the bismuth preparation recommended is bismuth subsalicylate in oil.

Sulfathiazole should be distributed to every public clinic for the treatment of gonorrhea. Purchased in quantity, this drug is relatively inexpensive, is very efficacious and is essentially devoid of untoward reactions within the dosage limits necessary to cure the patient with gonorrhea.

CASE FINDING AND CASE HOLDING

There are two effective methods of case finding: One deals with the routine serologic blood testing as a case finding device and the other the tracing through epidemiologic investigations of persons who have been intimately exposed to patients with communicable syphilis and gonorrhea.

Routine serologic blood testing should be encouraged by health officers as a valuable method of case finding in at least the following circumstances:

1. In all patients applying for medical care from hospitals or private physicians, including especially pregnant women.
2. In industry, where recognition of syphilis is a valuable measure in reducing industrial hazards and insurance losses. Periodic blood testing should be encouraged especially in industries in which there is a risk of life or injury to the syphilitic person or to others, or special need for the protection of property. However, blood testing of employees in selected industries such as food handlers, domestic servants, barbers and beauty parlor operators should not be utilized as an index

of infectiousness for other groups, and the testing of such employees is deplorable if they are singled out for undue discrimination.

3. In selected population groups; for example, the entire population of a county, not only as a method of individual case finding but also as a measure of the extent of the syphilis problem in the community.

4. In enrollees of the Army, Navy, Coast Guard, Civil Service and other federal agencies.

5. In candidates for marriage.⁶

In all these categories except the third the blood serologic test should be part of a general physical examination.

Refusal to submit to a serologic test and physical examination in industry should carry no penalty other than refusal of employment if such an examination is required as a prerequisite of original or continued employment. The discovery of syphilis should not per se penalize the person by refusal of employment or dismissal from employment.

The venereal diseases belong in the category of communicable diseases, and every new patient admitted to a treatment service offers a double challenge in case finding and case holding. If the infection is a relatively recent one, the search for its origin and for infections which may already have been transmitted by the patient to others should be begun at once. If the infection is an old one and the chance for finding extrafamilial contacts is remote, nothing less than full investigation of the patient's familial contacts should be considered adequate.

Case holding is essential if the infection is to be kept under control until the patient is cured. It is useless, however, to employ a case holding staff if the fundamental causes of neglect of treatment are ignored. Some of these are:

1. Failure to explain to the patient the nature of the infection and the importance of treatment in controlling communicability.
2. Failure to take into account the patient's economic problems and his ability to pay for private treatment.
3. Transportation difficulties in attending inconveniently located clinics.
4. Rough or discourteous handling of the patient in the clinic.
5. Lack of privacy in the clinic.
6. Dirty, crowded and unattractive clinic quarters.
7. Poor therapeutic technic which causes the patient pain and may result in untoward reactions.

Contact tracing and case holding may be performed by follow-up workers employed by the venereal disease clinic or by the health department. In either case, complete cooperation should be established to render the interviews in clinics most effective and to provide the health department with epidemiologic information necessary to insure the location of the contact or the defaulting patient. The competent follow-up worker should serve with such efficiency that it is necessary to bring formally to the attention of the health department only those patients or contacts who are noncooperative. The follow-up worker of the health department when assigned to epidemiologic work in clinics or for private physicians should serve as the agent of the clinic or the physician and not as the agent of the health department.

It is immaterial whether the follow-up worker is a public health nurse or a medical social worker. Much depends on the training and personal and professional qualifications of the individual. The minimum qualifications for public health nurses engaged in venereal

disease epidemiologic investigations have been defined by the members of the Conference of State and Territorial Health Officers and are available from the Surgeon General of the Public Health Service.

INFORMATIVE AND EDUCATIONAL PROGRAM

The informative program among physicians and other scientific workers should begin in the medical school for the physician and during the undergraduate technical collegiate training which the scientific worker receives, should be carried on during postgraduate training periods and should be applied continuously thereafter in an attempt to maintain the support of physicians in private practice and other scientific workers. In undergraduate and postgraduate courses in medicine and public health, the health officer and physicians specializing in the clinical management of syphilis and gonorrhea should encourage and promote the teaching of the most modern methods for the control and the clinical management of the venereal diseases. Those medical schools and teaching institutions which are especially prepared to train personnel in the control of the venereal diseases should be subsidized to make them better qualified for the task and to encourage research in this special field.

The health officer should make a special attempt to recruit interested and unusually competent personnel for service in the venereal disease control division. Eligible young physicians from among hospital interns should be selected and given postgraduate training in sufficient numbers to insure a continuous supply of venereal disease control officers in the state. Practicing physicians who cooperate with the health department in the control of the venereal diseases should also be given postgraduate training at public expense. Two types of training may be provided: (1) the short review course in current diagnostic and therapeutic practice and (2) the prolonged intensive training course to qualify the physician as a specialist.

Informative literature should also be provided for the health officer and the physician. This material should possess the following characteristics: 1. It should be interesting, scientific and brief. 2. Reprints should deal with special problems of diagnosis, treatment or after-care which are frequently met in routine practice. 3. Professional groups should receive copies of material used in the public educational program in order that physicians and other scientific workers may be encouraged to supplement by personal instruction the influence of the pamphlets prepared for popular distribution.

The educational program for the public is of paramount importance in promoting the use of public facilities made available for the control of the venereal diseases. Virtually all mediums of public communication—the press, radio, motion pictures, lectures, publications and graphic material—have been found effective in venereal disease education.

There is incomplete knowledge among health workers of the principles, practices and results of popular education pertaining to the control of the venereal diseases, as well as to public health in general. The Public Health Service has instituted a consultative and advisory plan to make available to local health departments the experience of trained educational workers in the field of venereal disease control who will collaborate with state or local health departments on request. Facilities for the production of all types of educational materials under the most strict professional standards

6. Two members of this advisory committee (Moore and Nelson) feel that for medical, social and political reasons blood testing compulsorily required by law is at present unwise in any category of patients.

of public health, editorial development and graphic treatment are also available to states through the Public Health Service. These consultation services should be utilized fully by state and local health departments to maintain a public interest in the control of the venereal diseases and to insure an accurate and effective educational program.

PROPHYLAXIS

Mechanical and local chemical prophylactic measures scientifically tested and applied are important factors in the prevention of the venereal diseases. Physicians, both in clinics and in private practice, should recognize that the proper use of a good prophylactic agent will usually prevent infection, and they should be encouraged to include instruction in the use of such agents when the need arises in their practice.

Particular reference is made to the published report of the Joint Committee on the Chemical and Mechanical Prevention of Syphilis and Gonorrhea, appointed by the American Social Hygiene Association and the Public Health Service.⁷ The conclusions expressed in these reports are in general regarded as sound.

PROSTITUTION AND THE SPREAD OF THE VENEREAL DISEASES

As with other communicable diseases, it is essential that persons who are actually or potentially infected with the venereal diseases should not be permitted to make promiscuous and unrestricted contacts which will spread the diseases to healthy people. This basic principle of epidemiology applies with the same force in the control of the venereal diseases as in the control of all other communicable diseases. The members of this committee, therefore, deplore the practice of toleration and segregation of prostitutes, either clandestine or professional, and urge that the proper repressive steps be taken by constituted police authorities. All health officers should cooperate with and encourage the police authorities in their jurisdictions to enforce existing laws prohibiting any person from engaging in prostitution or such related activities as procuring, solicitation and assignation.

The members of the Conference of State and Territorial Health Officers adopted comprehensive recommendations for the repression of prostitution throughout the United States. It is urged that all health officers follow these recommendations⁸ as a guide in the solution of the prostitution problem in their communities.

THE RELATIONSHIP BETWEEN VENEREAL DISEASE CONTROL AND SOCIAL HYGIENE

Social hygiene deals broadly with the study and solution of all human sex relationships and adjustments which are common in any civilization. It attempts to encourage practices which are recognized as good under the moral code and to destroy those which are bad. It has a very valuable place in the general program of public welfare but has a more limited yet very important place in public health.

All factors which lead to sexual promiscuity increase numerically the number of contacts, between infected, potentially infected and healthy persons and consequently are certain to result in an increase in the rates for syphilis and gonorrhea. It is therefore recom-

mended that all state and local health officers cooperate with and encourage the American Social Hygiene Association and affiliated local social hygiene societies.

PRESCRIBING DRUG CLERK AND THE CHARLATAN

Health officers and competent physicians should discourage the practice of counter-prescribing by drug clerks and the administration of treatment by practitioners who are not competent and qualified in the clinical management of the venereal diseases. Legislation to prohibit the administration of treatment by such persons should be enacted and governmental agencies established which will provide an inspection service to prevent such activities. In many states, a satisfactory inspection service may be organized under the food and drug administration of the state in cooperation with the state board of medical licensure, the state pharmaceutical board, the state medical and pharmaceutical associations and the state department of health.

VENEREAL DISEASE CONTROL IN THE NATIONAL DEFENSE PROGRAM

The venereal diseases still constitute the most serious public health problem in the development of the national defense program. Persons in the civilian population constitute alternate links in the chain of venereal disease infections in the armed forces. It is urged, therefore, that all health officers apply the principles set forth in the "Agreement by the War and Navy Departments, the Federal Security Agency and State Health Departments on Measures for the Control of the Venereal Diseases in Areas Where Armed Forces or National Defense Employees are Concentrated."⁹ This agreement was approved by the members of the Conference of State and Territorial Health Officers in May 1940.

FINANCING THE VENEREAL DISEASE CONTROL PROGRAM

The proportion of state and local health department funds to be allotted for the control of the venereal diseases should be sufficient to secure adequate protection of the public against the spread of these diseases by infected persons and to provide proper treatment, skilled medical care and maximum privacy for the individual patient. The responsibility of providing public funds lies with the state, the local and the federal governments. Both state and local appropriations, therefore, should be made available to supplement the federal funds which are allotted for this purpose. The Public Health Service should maintain its matching requirements at such a level that both state and local aid will be necessary throughout the country.

The Venereal Disease Control Act of May 24, 1938 requires that allotments be made to the several states on the basis of (a) the population, (b) the extent of the venereal disease problem and (c) the financial need. The same factors should be applied by the state health officer in the reallocation of funds for the control of the venereal diseases within the state.

Careful consideration should be given to the amount of money necessary to develop an optimum program for the control of venereal disease in a given community. It is important that the public be informed of this need if it is to support the appropriation of funds by legislative bodies for effective and economical use by the health department.

ADRENAL MEDULLA—CORI AND WELCH

GLANDULAR PHYSIOLOGY AND THERAPY

THE ADRENAL MEDULLA

CARL F. CORI, M.D.

AND
ARNOLD DEM. WELCH, M.D.
ST. LOUIS

This special article is published under the auspices of the Council on Pharmacy and Chemistry. It is one of a series which will be published in book form as the second edition of "Glandular Physiology and Therapy." The opinions expressed in this article are those of the authors and do not necessarily represent the views of the Council.—Ed.

Epinephrine has been studied extensively as a physiologic and as a pharmacologic agent. The subject has wide ramifications, and only what appear to be the most significant findings can be discussed in the space available.

ISOLATION OF EPINEPHRINE

The staining reactions described by Vulpian (green color with ferric chloride) and by Henle (brownish yellow color with dichromates) offered the first evidence for the presence in the medulla of the adrenal gland of a substance absent from most other tissues. Following the observation by Oliver and Schäfer¹ of the remarkable pressor effect of extracts of the adrenal medulla, intensive efforts were made to isolate the blood pressure-raising principle. Takamine² and Aldrich³ isolated the free base, while Abel⁴ reported the isolation of a crystalline substance, which was later shown to be a benzoyl derivative formed during isolation. The name "epinephrine," proposed by Abel for this derivative, was subsequently adopted as "official" for the natural substance. The term "adrenalin" is still trademarked in this country.

The correct empiric formula was determined by Aldrich⁵ and eventually shown, through the efforts of many workers and synthesis by Stolz⁶ and by Dakin,⁷ to represent the following structure.

INNERVATION OF MEDULLARY CELLS

It has been known since the work of Elliott,⁸ and his work has since been repeatedly confirmed, that the innervation of the adrenal medulla is of the preganglionic type, a finding consistent with the view that the medullary cells are modified absence of postganglionic fibers in the adrenal medulla (cat) and emphasizes the large number of roots which send fibers to the medulla; these fibers arise from at least the sixth to the sixteenth segment of the spinal cord and pass without synaptic interruption to the cells they innervate. The greater adrenal nerve conducts the majority of these fibers to the adrenal gland, where a network is formed in the connective tissue; after penetrating the cortex, without innervating it, the fibers end in intimate relationship with the medullary cells. Young found that each nerve fiber innervates a definite number of cells; in this manner units are formed which may conceivably be recruited much like the units of voluntary muscle.

Nerve Control of the Secretion of Epinephrine.—The preganglionic fibers supplying the adrenal medulla, like those to the sympathetic ganglia, are of the cholinergic type; i. e., on

stimulation they produce a substance pharmacologically indistinguishable from acetylcholine (Feldberg and co-workers¹⁰). A liberation of epinephrine from the adrenal medulla can be shown to follow a suitable injection of acetylcholine. The effects of splanchnic stimulation and of the injection of physostigmine, a drug known to inhibit the enzyme (esterase) responsible for the inactivation of acetylcholine. After the injection of physostigmine, acetylcholine when perfused through the isolated adrenal gland increases considerably the output of epinephrine (Heard and Welch¹¹).

The adrenal medulla, like the sympathetic ganglia, is not paralyzed by atropine in small doses. Nicotine, however, the typical effect of which is to paralyze all autonomic ganglia after transient stimulation of them, causes the adrenal medulla to fail to respond to splanchnic stimulation, after a short period of augmented secretion of epinephrine.

An increased discharge of epinephrine from the adrenal medulla has been demonstrated under a variety of conditions, among which may be mentioned stimulation of sensory nerves, states of fear and rage, muscular activity, asphyxiation, hemorrhage, hypoglycemia, application of excessive heat or cold and administration of convulsant drugs (strychnine, picrotoxin, inhalation anesthetics (chloroform and ether), morphine (in cats and dogs) and histamine (for literature, see Trendelenburg¹²). In many of these cases the epinephrine content of the adrenal medulla (which represents a balance between the rate of new formation and the rate of discharge) is found to be diminished.

Sectioning of the splanchnic nerves, the principal efferent arm of the reflex arc, abolishes or greatly diminishes the discharge of epinephrine. The central connections, however, are not definitely known. Stimulation of certain hypothalamic areas is followed by an increase in secretion of the hormone,¹³ as well as by other manifestations of sympathetic hyperactivity. The prolonged hyperglycemia and hyperlactacidemia which follow the piqûre of Claude Bernard are due in large part to liberation of epinephrine from the adrenal medulla.

Whether there is a basal rate of secretion of epinephrine has perhaps not been unequivocally established, but it is probably safe to conclude that so long as nerve impulses reach the medullary cells epinephrine is liberated. The physiologic significance of such secretion of epinephrine appears to be small, since denervation of the adrenals or even complete sympathetomy does not lead to notable functional disturbances under normal environmental conditions. The increased discharge of epinephrine under conditions of stress is regarded by Cannon and his school¹⁴ as an emergency function; it serves to reinforce the activity of the sympathetic nervous system and causes a variety of circulatory and metabolic adjustments which (by a priori reasoning) are assumed to be useful to the organism. The evidence presented may be summarized by saying that the adrenal medulla consists of modified sympathetic ganglion cells under the control of cholinergic preganglionic fibers arising in the thoracolumbar portion of the spinal cord, and that secretion of epinephrine is normally dependent on the degree of activity of these fibers.

SYMPATHOMIMETIC ACTION OF EPINEPHRINE

The action of epinephrine on a given tissue may be inhibitory or excitatory; it is identical, however, with the effect produced by stimulation of the sympathetic fibers supplying the tissue, provided the fibers are of the adrenergic type, i. e., on stimulation, produce an epinephrine-like substance.¹⁵ A change in the effect of sympathetic stimulation—for example, from an inhibitory effect on the uterus of the nonpregnant cat to an excitatory effect in the pregnant animal—is paralleled by a similar change in the response to epinephrine. Some of

15. Some sympathetic fibers, e. g., those innervating the sweat glands of some species, are cholinergic, and the effect of their stimulation is therefore "mimicked" by the injection of acetylcholine chloride and not by that of epinephrine hydrochloride.

ADRENAL MEDULLA—CORI AND WELCH

the more important "sympathomimetic" actions of epinephrine are represented in constriction of arterioles, acceleration of the heart rate, contraction of the radial muscle of the iris and of the nictitating membrane, salivary secretion, relaxation of bronchial musculature, inhibition of the small intestine and inhibition of the uterus and bladder (in certain species).

When the sympathetic fibers supplying smooth muscle or other tissues are cut and sufficient time is allowed for degeneration of the peripheral segments, the action of epinephrine is not abolished;¹⁶ this indicates that epinephrine does not act on the nerve endings of these fibers. It is incorrect to conclude, however, that epinephrine acts directly on smooth muscle fibers; a number of drugs act in this manner (for instance, barium ions), but their effect does not parallel that of sympathetic stimulation. Elliott¹⁷ suggested that the union of the sympathetic nerve fiber with the muscle fiber causes the development of a special structure, the "myoneural junction," which is neither nervous nor contractile but which renders the associated cell peculiarly sensitive to epinephrine. When this structure has once developed as the result of innervation,¹⁸ it remains intact despite denervation and the cell retains its sensitiveness to epinephrine. Clark¹⁹ has shown that the amount of epinephrine taken up by isolated tissues when a measurable effect is produced is so small that only a small fraction (less than 1 per cent) of the cell surface could be occupied. This leads to the concept that epinephrine acts on certain specific receptors in the cell, which (in the case of smooth muscle) are in intimate relation with the contractile mechanism.

Transmission of Nerve Impulses.—It is generally assumed that there exists discontinuity between the termination of the nerve fibers and the muscle cell, and the question arises how stimulation of sympathetic nerve fibers can produce the same effect as epinephrine. Two theories have been proposed for the transmission of nerve impulses, one electrical and the other chemical; only the latter, which had its inception in the work of Loewi,²⁰ is within the scope of this review.²¹

According to the humoral transmission theory, an epinephrine-like substance is liberated at the termination of the sympathetic "adrenergic" fibers. This chemical mediator (which seems to be identical with epinephrine) reaches the receptor mechanism of the cell by diffusion; there it combines with a specific substance E if the effect is excitatory and with a specific substance I if the effect is inhibitory. Cannon and his school²² have shown that the products of these combinations, "sympathin E" and "sympathin I," may escape from the site of their formation and be carried by the blood stream to distant tissues, where they produce effects which differ from each other and from effect of epinephrine. For example, sympathin E released by stimulation of the hepatic nerve fibers has a pressor action and causes contraction of the nictitating membrane but, unlike epinephrine, produces no significant pupillary dilatation or relaxation of the uterus of the nonpregnant cat. Certain drugs (ergot alkaloids, yohimbine and synthetic dioxane derivatives), which abolish the pressor effect of epinephrine have little effect on the rise in blood pressure produced by sympathin E (released as the result of stimulation of hepatic or lumbar nerve fibers). It has been shown recently that stimulation of sympathetic nerve fibers supplying the rabbit ear results in liberation not only of an epinephrine-like substance but also of a compound closely resembling histamine,²³ both detectable in the venous

blood of the ear. This suggests that the "sympathin E" and "sympathin I" effects may conceivably be resultants of release of more than one pharmacologically active substance. When adrenergic nerve trunks are stimulated in vitro an epinephrine-like substance diffuses into the surrounding medium (Lissák²⁴). Several authors who found an epinephrine-like substance in extracts of various tissues probably obtained this material from the adrenergic fibers contained in the tissue, since, as Cannon and Lissák have shown, degeneration of the sympathetic fibers supplying a tissue (heart or liver) results in the disappearance of the sympathomimetic

substance. Lissák²⁶ reported that when the preganglionic (cholinergic) fibers of the superior cervical ganglions (cat) are cut, there occurs, after a week or two, a disappearance of the acetylcholine which is normally present, while a substance with the properties of epinephrine remains in the ganglion. These observations show that adrenergic neurons are characterized by the presence of epinephrine (or a substance closely resembling this principle in its pharmacologic and chemical properties) in cell bodies, axons and their terminations and by the liberation of epinephrine during nerve activity. The situation is similar to that obtaining in cholinergic neurons, in which acetylcholine is the characteristic substance that acts on the receptor mechanism of the (muscle or gland) cell. However, a collection of specially differentiated cells containing acetylcholine and displaying an auxiliary function comparable to that which the adrenal medulla bears to the adrenergic system has not been demonstrated.

16. As a matter of fact, it is greatly increased. When one eye is sympathetically denervated and the other kept as a control, doses of intravenously injected epinephrine hydrochloride which dilate the pupil of the denervated eye have no effect on the normal eye. Denervated structures (eye, heart, blood vessels) have been used as sensitive indicators of an increased discharge of epinephrine from the adrenals.
17. Elliott, T. R.: *J. Physiol.* **32**: 401, 1905.
18. It is of interest that placental vessels, which have no nerve supply, respond to epinephrine and acetylcholine very weakly. This supports Elliott's idea of the development of a special receptor substance under the influence of innervation.

An integral part of the humoral transmission theory (if it is to account for the observed bioelectric phenomena) is not only the formation of the chemical mediator but also the inactivation of this principle at the site of action. Observations concerning the formation, stabilization and destruction of epinephrine will be reviewed briefly.

FORMATION OF EPINEPHRINE

The most likely precursor of epinephrine (see table, no. 1) is phenylalanine (table, no. 2), one of the amino acids known to be indispensable at least for growth (rats). The introduction of two hydroxyls (in positions 3 and 4) into the benzene ring is an essential step in the synthesis of epinephrine from phenylalanine. The body readily introduces the first hydroxyl, converting phenylalanine to tyrosine (table, no. 3), but the mechanism of insertion of the second hydroxyl has remained obscure. An enzyme, tyrosinase, which has the specific property of introducing this second hydroxyl into tyrosine, converting it to dihydroxyphenylalanine (dopa) (table, no. 4), occurs in plants but has not been found in mammalian tissues. Recently, however, Arnow²⁷ has shown that ultraviolet radiation in vitro converts tyrosine into dihydroxyphenylalanine, a reaction which is catalyzed by Fe⁺⁺ ions (Rothman²⁸); a similar reaction in the skin might furnish the necessary precursors for the formation of epinephrine, as well as for the formation of melanin, the pigment of human skin.²⁹ Heard and Raper,³⁰ in a study of the oxidation of N-methyl tyrosine (table, no. 5) by tyrosinase, found, in addition to melanin, a small amount of pressor substance, the activity of which was increased by hydrogenation, suggesting that adrenalone (table, no. 6) had been formed. One possible pathway of the synthesis of epinephrine might therefore be the formation of dihydroxyphenylalanine, the oxidation of the β -carbon of the side chain with formation of a hydroxyl group, methylation of the amino group and finally decarboxylation. Enzymes responsible for these reactions have not been isolated from mammalian tissues. Incubation of adrenal medullary tissue with a number of possible precursors of epinephrine (tyramine [table, no. 7],³¹ phenylethylamine [table, no. 8],³² dihydroxyphenylethylamine (dopamine) [table, no. 9]³³) has not, so far, yielded results of great value in the elucidation of the synthesis of epinephrine.

STABILIZATION AND DESTRUCTION OF EPINEPHRINE

It has long been known that epinephrine is much more stable in blood than in Ringer's solution and that many other tissues contain substances which exert a protective action on the hormone. Several authors have studied the stabilizing effect of amino acids on epinephrine. This is not accomplished through the formation of complexes, as was suggested by Wiltshire,³⁴ but through the amino acids serving as hydrogen donors to the quinone of epinephrine (table, no. 10), a portion of which is thereby reduced to epinephrine (Welch³⁵). In this manner the rate of destruction of epinephrine is decreased. Much more effective than amino acids are glutathione and ascorbic acid, two reducing substances which are present in most tissues; they prevent the irreversible oxidation of epinephrine by molecular oxygen³⁵ and by the widely distributed cytochrome—cytochrome oxidase system.³⁶ The high concentration of ascorbic acid and of glutathione in the adrenal gland may be related to the stabilization of the hormone either in the gland or in the blood leaving it. Heard and Welch¹¹ showed that perfusates of the adrenal gland always contain ascorbic acid; in such perfusates the pressor activity remains unchanged as long as reduced ascorbic acid is present. With completion of the

oxidation of ascorbic acid, the red color of oxidized epinephrine appears, followed by a progressive decrease in pressor activity.³⁷

It is very unlikely that nonenzymatic auto-oxidation of epinephrine represents a mechanism by which epinephrine is inactivated in the tissues. In vitro it has been shown that heavy metal ions and an alkaline reaction favor this auto-oxidation. Ball and Chen³⁸ showed that there is first formed an extremely unstable quinone (table, no. 10); apparently this undergoes internal oxidation-reduction and rearrangement to form an unstable indole derivative, called adrenochrome:³⁸

Various oxidizing agents form adrenochrome or derivatives of it (e. g., iodoadrenochrome) from epinephrine. The red color which develops in solutions of epinephrine is probably due, at least in part, to the formation of adrenochrome, a substance which is pharmacologically inactive. Green and Richter³⁶ have demonstrated the oxidative formation of adrenochrome from epinephrine through catalysis by hematin derivatives and by the cytochrome—cytochrome oxidase system. Of particular significance is the observation that the sympathomimetic 3, 4 dihydroxybenzene derivatives most rapidly destroyed in vivo are also those most rapidly oxidized by this system, which may well be concerned with the physiologic inactivation of epinephrine.³⁹

In addition to this enzyme system which attacks the catechol (table, no. 11) portion of the molecule, there is present in mammalian tissues another enzyme, amine oxidase,⁴⁰ which attacks a multitude of amines, converting them to aldehydes and ammonia (in the case of epinephrine, methylamine is formed instead of ammonia). The oxidation of epinephrine by this enzyme is apparently not inhibited by reducing substances.

Ephedrine (table, no. 12), benzedrine (table, no. 13), veritol (table, no. 14) (and other substances related to epinephrine, with a methyl group attached to the carbon adjacent to the nitrogen) are not attacked by this enzyme but are able to compete with epinephrine and the sympathetic mediator for amine oxidase, thus protecting them from destruction. Gaddum and Kwiatkowski⁴¹ demonstrated that epinephrine and the sympathetic mediator are strikingly potentiated by ephedrine in their action on the blood vessels of the rabbit ear and explain this effect as due to the inhibition of amine oxidase. In agreement with this interpretation are the observations that denervation of blood vessels and of the iris, procedures which abolish the formation of the sympathetic mediator, greatly diminish the action of ephedrine and that the action of ephedrine is restored when epinephrine is present in the circulation.⁴² Morton and Tainter,⁴³ in a detailed study of the action of ephedrine on blood vessels, found most of the results compatible with the view that this substance inhibits amine oxidase.

Richter⁴⁴ reported recently that orally administered d-epinephrine and l-epinephrine are mainly eliminated as conjugated derivatives in the urine, from which he concludes that conjugation with sulfate is the main physiologic process by which epinephrine is inactivated in the body.

Several other enzymes are capable of oxidizing epinephrine (e. g., catechol oxidase, peroxidase, tyrosinase), but these have rarely if ever been found in mammalian tissues. Bacq⁴⁵ claimed

37. Addition of ascorbic acid to isolated tissues does not intensify or prolong the action of epinephrine, presumably because considerable amounts of reducing substances are present in the tissues to begin with. It seems necessary to assume that there exists in the tissues a mechanism for the destruction of epinephrine which is not inhibited by reducing substances.

38. Ball, E. G., and Chen, T.: *J. Biol. Chem.* **102**: 691, 1933.

39. It is of interest that epinephrine can replace flavoprotein as a carrier in certain enzyme systems which reduce diphosphopyridine nucleotide (e. g., lactic dehydrogenase); this property is dependent on the oxidation of epinephrine to adrenochrome.

that a catechol oxidase is present in the smooth muscle of the uterus, but this has not been confirmed by Lissák⁴⁰ and others. The evidence available at present points to the cytochrome—cytochrome oxidase system—and to amine oxidase as the enzymes principally concerned with the physiologic inactivation of epinephrine.

RELATION BETWEEN CHEMICAL STRUCTURE AND ACTION

In a large number of investigations, among which those of Barger and Dale⁴⁷ may be mentioned particularly, it has been made clear that nearly all compounds with relatively simple substitution of the phenylethylamine skeleton (table, no. 8) possess some sympathomimetic action. The role of the various groupings may be summarized as follows: The catechol portion (table, no. 11) of the molecule enables it to undergo oxidation to a quinone, with indole rearrangement, adrenochrome formation and loss of physiologic activity. The greater stability of many of the synthetic sympathomimetic compounds in clinical use may be attributed to the absence of one or both of the hydroxyls found on the benzene ring of epinephrine.

The hydroxyl group on the carbon atom adjacent to the benzene ring confers optical activity on the molecule; this is of significance since the naturally occurring or l-epinephrine is approximately fifteen times as active as the d-isomer. It may be pointed out here that none of the numerous synthetic compounds related to epinephrine has a pressor activity greater than that of the naturally occurring principle, although some possess definite advantages for one or another therapeutic use. Another possible role for the hydroxyl group in the side chain might be related to ester formation. There is some evidence for the presence of a precursor of epinephrine in the adrenal medulla, and an ester involving this group might be expected to yield epinephrine readily.

The significance of the methyl group in epinephrine is obscure; the pressor activity of the demethylated compound (norepinephrine or arterenol [table, no. 15]) differs but little from that of epinephrine. Barger and Dale⁴⁷ pointed out that N-methyl epinephrine-like compounds excel as "inhibitors," while the corresponding unmethylated amines are often superior in producing "augmentation." This has led to the suggestion that sympathin E might be norepinephrine, but the results obtained by Gaddum and Kwiatkowski⁴¹ do not support this view.

HEMODYNAMIC EFFECTS OF EPINEPHRINE

The blood pressure response to intravenously injected epinephrine hydrochloride is characterized by a very short latent period, a dependence of the magnitude of the response on the dose (within certain limits) and a rapid return to normal. When epinephrine is liberated from the adrenals or when epinephrine hydrochloride is injected intravenously, it must pass through the right chambers of the heart, the pulmonary circulation and the left chambers of the heart before reaching the systemic vascular bed. It is of importance, therefore, that the blood vessels of the lung are relatively insensitive to the constrictor action of epinephrine and that the coronary vessels of the heart are actually dilated by the drug. The additional work of the heart during a rise in blood pressure could not be sustained without the increased oxygen supply that the dilated coronaries afford. Similarly, the greatly increased flow of blood through a working skeletal muscle is not interfered with by pressor doses of epinephrine hydrochloride and the flow through resting muscle may actually be increased by small doses.

The most intensive effect of epinephrine is on the arterioles, which are richly endowed with smooth muscle supplied with sympathetic (adrenergic) nerves. The constriction of these vessels, particularly in the splanchnic area, causes increased resistance to the circulation of the blood, as a result of which the blood pressure

begins to rise. In the excised heart epinephrine causes an increase in rate and contractility; in the intact animal this effect of epinephrine is less marked, because the rising blood pressure, through stimulation of the pressor receptors of the carotid sinus and the aorta and the resultant vagal reflex, depresses the cardiac rate. When the pressor reflex mechanism is abolished by section of the vagi or by atropinization, a given dose of epinephrine hydrochloride causes a much greater rise in blood pressure and acceleration of the heart rate than when the reflex mechanism is intact.

During the abrupt initial rise in blood pressure the output of the heart probably decreases; this is followed, however, by an increase in cardiac input and output when the blood expressed from the contracted splanchnic area and the spleen has reached the left cavities of the heart, and by a marked increase in the rate of blood flow. As a result of the changes outlined, the circulatory system may be said to operate at a "higher level" with increases in blood flow, circulating blood volume and blood pressure.

The effect of a single intravenous injection of epinephrine hydrochloride is of short duration. Continuous injection of the drug may be used to maintain blood pressure at an elevated level for long periods, the level depending on the amount injected per unit of time. The minimal rate of constant intravenous injection (in milligrams per kilogram per minute) which causes a rise in blood pressure is 0.00005 in man, 0.0005 in dogs, cats and rabbits and 0.001 in rats (Cori⁴⁸).⁴⁰ These figures show that the vascular system of man is more sensitive to the action of epinephrine than that of other species. In the laboratory animals mentioned, subcutaneously injected epinephrine hydrochloride does not cause a rise in blood pressure; in man, however, such injection of the drug (0.5 to 1 mg.) is generally followed by a rise in systolic blood pressure⁵⁰ (10 to 30 mg. of mercury), in pulse rate (10 to 20 beats per minute), in minute volume of the heart (20 to 70 per cent) and in the volume of respiration (50 to 100 per cent), effects which reach their maximum after one-half hour and disappear after one to two hours; extrasystoles are often noted.

METABOLIC EFFECTS OF EPINEPHRINE

The chief metabolic changes which result from the administration of epinephrine are increases in blood sugar, blood lactic acid and basal metabolic rate. Procedures which cause an increased discharge of epinephrine from the adrenals (see a preceding section) lead to the same metabolic changes. The maximal rate at which epinephrine is discharged from the adrenals during splanchnic stimulation in cats has been shown to be 0.003 mg. per kilogram per minute;⁵¹ this procedure causes a decided rise in blood pressure. It should be emphasized that metabolic changes may be produced in unanesthetized dogs, rabbits and cats by intravenous injection at the rate of 0.0002 mg. per kilogram per minute, i. e., at a rate which does not cause a rise in blood pressure. Furthermore, subcutaneous injection of epinephrine hydrochloride in these species causes hyperglycemia and glycosuria without changes in blood pressure. In man, epinephrine hydrochloride injected

48. Cori, C. F.: *Physiol. Rev.* **11**: 143, 1931.

49. It should be emphasized that epinephrine hydrochloride when injected in doses too small to raise blood pressure may nevertheless cause well defined vascular changes; i. e., the vessels of the skin may contract while those of muscles are dilated.

50. The diastolic blood pressure often decreases in man following the subcutaneous injection of epinephrine hydrochloride, because of vasodilatation in certain vascular areas, particularly in muscle.

51. Cannon, W. B., and Rapport, D.: *Am. J. Physiol.* **58**: 308, 1922.

46. Lissák, K.: *Science* **57**: 371, 1938.

47. Barger, G., and Dale, H. H.: *J. Physiol.* **41**: 19, 1910.

intravenously at the rate of 0.00005 mg. per kilogram per minute causes a rise in blood sugar as well as in lactic acid and in basal metabolic rate.⁵² In all species this rise is detectable a few minutes after the start of the injection, continues while the injection is being made and slowly subsides following the cessation of the injection. The lowest rate of intravenous injection which causes a rise in blood sugar also causes a rise in blood lactic acid. Within a certain range there is a parallelism between rate of injection and magnitude of response.

A single intravenous injection, even of a large dose, produces metabolic changes of only moderate intensity, while the same dose when injected slowly during two hours causes marked hyperglycemia and hyperlactacidemia. For example, a rabbit responded to a single intravenous injection of 0.03 mg. per kilogram with a maximal rise in blood sugar of 60 mg. and in blood lactic acid of 10 mg. per hundred cubic centimeters; the same dose when injected at a rate of 0.00025 mg. per kilogram per minute for one hundred and twenty minutes (0.03 mg. per kilogram) caused a rise in blood sugar of 180 mg. and in lactic acid of 32 mg. per hundred cubic centimeters. In the latter case the conditions are comparable to subcutaneous injection, a procedure which, owing to continuous absorption of the drug from the subcutaneous depot, causes intense and prolonged hyperglycemia in rabbits.⁵³ These observations emphasize the fact that epinephrine is rapidly inactivated in the body and that a prolonged effect is dependent on a continuous supply of the drug. Since epinephrine is quite stable in the blood itself, this inactivation must occur in other tissues, presumably at the site of action of the drug. The liver has been shown to be an important organ for the inactivation of epinephrine, but rapid inactivation occurs even in hepatectomized animals.

Epinephrine accelerates the rate of enzymatic breakdown of glycogen in liver and muscle, the end products of this breakdown being dextrose in the former and lactic acid in the latter case.⁵⁴ The formation of blood sugar and lactic acid from glycogen follows a common initial pathway, namely:

The first of the aforementioned reactions represents a reversible enzymatic equilibrium; it has been shown that the direction in which the reaction proceeds (i. e., whether it goes to the right or to the left) is determined by the relative concentrations of inorganic phosphate and glucose-1-phosphate. The second reaction, the enzymatic conversion of glucose-1-phosphate to glucose-6-phosphate, accelerates the breakdown of glycogen by disturbing the equilibrium of the first reaction. In liver glucose-6-phosphate is acted on by a phosphatase which splits the ester to glucose and inorganic phosphate; in muscle, which does not contain an active phosphatase, the ester is converted to lactic acid.⁵⁵

The formation of lactic acid is secondary to the accumulation of hexosemonophosphate. When isolated frog muscles are immersed in Ringer's solution containing epinephrine hydrochloride in a concentration of 1:10,000,000, there occur a decrease in glycogen, an increase in hexosemonophosphate and a corresponding decrease in inorganic phosphate; only a small amount of lactic acid is formed.⁵⁶ The same changes are observed in mammals when epinephrine is injected subcutaneously, except that a greater part of the muscle glycogen which is broken down is converted to lactic acid. The decrease in the inorganic phosphate of the blood which is observed in mammals following the injection of epinephrine hydrochloride is due to the accumulation of hexosemonophosphate in muscle. The drop in serum potassium which takes place, after a short initial rise, may also be connected with the accumulation of hexosemonophosphate.

In postabsorptive rats subcutaneously injected epinephrine hydrochloride caused a decrease in muscle glycogen and an increase in hepatic glycogen three hours after injection. When the course of this reaction was studied, it was found that fifteen minutes after the injection of epinephrine hydrochloride the hepatic glycogen had decreased, that it reached the original level after one hour and that it exceeded the original level three hours after the injection; muscle glycogen, which decreased initially, remained low throughout the period of observation. The explanation of these findings is that the lactic acid which is formed from glycogen in muscle escapes into the blood stream and is carried to the liver, where it is converted back to glycogen. Initially the rate of glycogen breakdown in the liver exceeds that of glycogen formation, but later this is reversed, so that the end effect of an injection of epinephrine hydrochloride is a redistribution of glycogen, an increase in hepatic glycogen at the expense of muscle glycogen.⁴⁸ The same changes in the distribution of glycogen, with somewhat different time relations, have been observed in rabbits.

The immediate effect of epinephrine on the blood sugar level depends on the content of glycogen in the liver. The hyperglycemic response is much smaller in animals with low hepatic glycogen than in those with large glycogen stores. The maintenance of an elevation of the blood sugar level for longer periods depends on the supply to the liver of material from which new carbohydrate (liver glycogen and blood sugar) can be formed. Injections of epinephrine do not cause increased excretion of nitrogen in the urine, which indicates that protein is not the source of the newly formed carbohydrate. Balance experiments in normal animals have shown that the decrease in muscle glycogen is of sufficient magnitude to account for the newly formed carbohydrate in the liver. In depancreatized dogs injections of epinephrine hydrochloride cause excretion of a large amount of extra sugar in the urine, which is largely derived from muscle glycogen. One may conclude that epinephrine is able to maintain an elevation of the blood sugar level partly by accelerating the breakdown of liver glycogen and partly by accelerating the transformation of muscle glycogen to lactic acid, which serves as a source of new carbohydrate.

The mobilization of glycogen by epinephrine is of importance during hypoglycemia. It has been shown that hypoglycemia evokes an increased discharge of

52. Cori, C. F., and Buchwald, K. W.: *Am. J. Physiol.* **95**: 71, 1930.

53. In hypophysectomized animals the absorption of subcutaneously injected epinephrine hydrochloride is so slow that hardly any hyperglycemia occurs; intravenous injection of the drug has the same hyperglycemic action in these animals as in normal animals (Russell, J. A., and Cori, G. T.: *Am. J. Physiol.* **119**: 167, 1937).

54. Ergot alkaloids inhibit glycogenolytic action in the liver but have no effect on lactic acid formation in muscle.

55. Cori, C. F.: *Endocrinology* **26**: 285, 1940.

56. Hegnauer, A. H., and Cori, G. T.: *J. Biol. Chem.* **105**: 691, 1934.

epinephrine from the adrenals.⁵⁷ Animals with denervated adrenals are hypersensitive to the hypoglycemic action of insulin; convulsions are produced with smaller doses and the original blood sugar level is regained more slowly than in animals in which the mechanism for the discharge of epinephrine is intact. These experiments demonstrate the participation of epinephrine in the regulation of the blood sugar level under conditions of stress. Under more normal conditions medulladrenalectomized and sympathectomized dogs are able to regulate their blood sugar as efficiently as animals that have not been operated on.⁵⁸

Epinephrine increases the oxygen consumption from 15 to 30 per cent in the fasting, in the postabsorptive and in the dextrose-fed animal. In the first the extra calories are derived exclusively from oxidation of fat; in the postabsorptive animal, in which a mixture of carbohydrate and fat is being oxidized, epinephrine also increases the metabolism without much change in the proportion of the foodstuffs burned. During absorption of dextrose in previously fasting rats epinephrine actually decreases oxidation of carbohydrate and the extra calories are furnished by oxidation of fat. The calorogenic action of epinephrine may represent, in part at least, the cost of reconversion of lactic acid to carbohydrate, a process which is known to require energy.⁴⁸

	Liver Glycogen	Glycogen in Rest of Body	Tissue Sugar	Carbo- hydrate Oxidized	Blood Sugar per 100 Cc.
Controls	—49	—167	—22	220	—45
Epinephrine	+26	—298	+8	263	+16
Insulin	—141	—188	—47	434	—89

The elevation of the blood sugar level during epinephrine action does not signify that oxidation of carbohydrate is correspondingly increased.⁵⁹ In man, Conn and associates⁶⁰ found that at a blood sugar level of 200 mg. per hundred cubic centimeters produced by injection of epinephrine hydrochloride, less dextrose was oxidized than when no epinephrine was given and the blood sugar was 80 mg. per hundred cubic centimeters. When the blood sugar was raised to the same level in one instance by injecting epinephrine hydrochloride and in another by feeding dextrose, twice as much sugar was oxidized in the latter as in the former case. Courtice and co-workers⁶¹ found that in man under postabsorptive conditions epinephrine hyperglycemia is not associated with an increase in oxidation of sugar, and the same result was obtained by Dill and collaborators.⁶² Lundsgaard and associates⁶³ reported that the increase in utilization of dextrose which occurs in a perfused hind limb preparation of a dog at a high blood sugar level is prevented by epinephrine.

The difference in the action between epinephrine and insulin is illustrated in the following experiments, in which these substances were injected into rats immediately after the completion of absorption of a sugar

meal.⁶⁴ The changes which occurred during the first three hours after the injection are expressed in milligrams per hundred grams of rat.

Epinephrine, in spite of a raised level of blood sugar, has little effect on oxidation of carbohydrate and increases mainly the disappearance of muscle glycogen, which is partly oxidized and partly converted to lactic acid and hence to liver glycogen and blood sugar. Insulin doubles oxidation of carbohydrate, and the material drawn on is mainly blood sugar derived from liver glycogen. The opposite effects of epinephrine and insulin on the blood sugar level are clearly reflected in the rate at which blood sugar is oxidized in the tissues. Insulin enables the tissues to oxidize blood sugar at an increased rate, even when the concentration is below normal; epinephrine prevents the increase in oxidation of blood sugar which is normally associated with a rise in the concentration of this sugar.

Anesthetics, particularly barbiturates, greatly enhance the effect of epinephrine on the utilization of blood sugar, as shown in the following experiments. Unanesthetized rats metabolized 98 per cent, and when treated with epinephrine, 88 per cent, of the dextrose supplied them in four hours. During amytal anesthesia 91 per cent was utilized, but when epinephrine was injected during amytal anesthesia, only 33 per cent was utilized, and the rest of the sugar was excreted in the urine.⁶⁵ The mechanism by which barbiturates enhance the inhibitory effect of epinephrine on the utilization of dextrose is not known.

THERAPEUTIC USES OF EPINEPHRINE

Extensive use is made of the vasoconstrictor action of epinephrine hydrochloride; the drug is applied locally to congested mucous membranes and to bleeding surfaces; it is injected in combination with various local anesthetic agents to reduce blood flow through the tissues receiving the injection and thus to delay absorption. This use permits a minimal concentration of the anesthetic compound to be employed, reducing the danger of systemic effects; it also prolongs the duration of local anesthesia and reduces bleeding following incision.

Epinephrine usually gives relief in a variety of allergic disorders which are thought to be due to the liberation of a histamine-like substance; it counteracts the urticaria and other manifestations of serum sickness; it counteracts the acute circulatory disturbance (nitritoid crisis) which is sometimes seen following an injection of any of the arspenamines. In cases of angioneurotic glottis edema the drug may be life-saving. In asthmatic attacks epinephrine usually gives prompt relief, due to its dilator action on the bronchial musculature. In shock the drug is of little value, and may actually be harmful; the arterioles, on which epinephrine principally acts, are already maximally constricted as a result of the state of shock, while the constrictor action on the dilated capillaries is too feeble to displace the blood which stagnates in the splanchnic area.

Spectacular is its occasional successful use in resuscitating persons in whom the heart has apparently ceased to beat as a result of drowning, carbon monoxide poisoning or accidents during anesthesia. In such cases, justifying heroic measures, intracardiac injections of epinephrine hydrochloride have sometimes resulted in the initiation of cardiac contractions. Epinephrine is used in Stokes-Adams disease to increase the idioventricular rate.

58. Brouha, L.; Cannon, W. B., and Dill, D. B.: *J. Physiol.* **95**: 431, 1939.

59. The lactic acid formation results in a lowering of the carbon dioxide-combining power of the blood. Experiments in which respiratory metabolism is measured have to be extended to a time when the acid-base equilibrium has returned to the original level; or the proper corrections for the extra carbon dioxide given off have to be made.

COUNCIL ON PHYSICAL THERAPY

JOUR. A. M. A.
JUNE 7, 1941

Intravenous injections of epinephrine hydrochloride are potentially dangerous, particularly in patients with hypertension. The sudden rise in blood pressure may cause acute cardiac dilatation in a weakened heart; it may lead to rupture of atheromatous blood vessels and intensify the severity of internal hemorrhages; it is often followed by a prolonged period of low blood pressure. In animals, paralysis of the central nervous system and edema of the lung are terminal symptoms of an overdose of epinephrine, and similar symptoms have been observed in man. Under certain conditions injections of epinephrine hydrochloride have been shown to cause fatal ventricular fibrillation; best known of conditions predisposing to such an occurrence is light chloroform anesthesia.

Most of the desirable systemic actions of the drug can be secured by subcutaneous administration; this is safer than intravenous injection, and the action is of longer duration. It should be mentioned, however, that absorption of epinephrine hydrochloride from subcutaneous tissues may be deficient in persons with failing circulation. Massage of the injected area has a marked effect on the rate of absorption, as shown by the immediate blood pressure response. If a prolonged systemic action is desired, epinephrine suspended in oil may be injected subcutaneously or intramuscularly.⁶⁶ For certain therapeutic purposes, intravenous injection at a constant rate (in contrast to single intravenous injections) has been used but it requires a special apparatus, the addition of some stabilizer to prevent in vitro oxidation of the drug, and repeated control of blood pressure.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
HOWARD A. CARTER, Secretary.

CONNELL GAS MACHINE DeLuxe TABLE MODEL ACCEPTABLE

Manufacturer: Connell Division, Ohio Chemical and Manufacturing Company, 1177-1199 Marquette Street, N.E., Cleveland.

The Connell Gas Machine, DeLuxe Table Model, is designed for the administration of inhalation anesthesia by (a) "absorption in circuit" or (b) "absorption to-and-fro."

Cylinders of gases, D size or smaller, or piped gases under low pressure may be utilized in the apparatus. No automatic reducing valves are used. Leaks from cylinder to cylinder can not occur. There are yokes for six gas supplies, each with its own control valve; two are labeled "oxygen," two are labeled "Filler—He, N₂O, CO₂" (helium, nitrous oxide, carbon dioxide) and two are labeled "Anesthetic—N₂O, C₂H₆, C₃H₈" (Nitrous oxide, ethylene, cyclopropane). Three dry flowmeters are incorporated; one is for oxygen, reading to 1,000 cc. per minute in fine scale and thence to 8 liters per minute on the coarse scale, and the second meter measures the "Filler—He, N₂O, CO₂" (helium, nitrous oxide, carbon dioxide). The third meter measures the anesthetic agent and has a reversible scale reading to 800 cc. per minute on one side for ethylene, and to 10 liters per minute on the opposite side for nitrous oxide. From the tube of the breathing circuit built into the "inspiratory" tube of the to-and-fro absorber is used, the gases flow out this "inspiratory" tube by a single hose to the "to-and-fro absorption" unit. Very large, unmeasured amounts of gases may flow through the meters.

When used for carbon dioxide absorption in circuit, the progress of the respired atmosphere is as follows: Expired gases leave the face mask by one large tube, pass through a one-way gravity type flutter valve, thence through the soda lime canister, then through another one-way gravity type flutter valve through the inspiratory tube and back to the face mask. A drip-type ether vaporizer is attached to the inspiratory side of the circuit near the gas feed, the ether dripping onto a small plate in the large tube. The breathing bag is attached to the circuit between the soda lime canister and the gas feed. Two types of breathing bags are provided; one is a pendant bag of about 3 liters capacity, and the other an accordion type bag with the gas inlet at the bottom. By means of a rod attached to the top of the latter bag and projecting through the top of the apparatus, the tidal volume of breathing can be read against the scale, marked to 3 liters capacity. The soda lime canister is easily changed without interrupting anesthesia by loosening a thumb screw holding it in place with the gases shunted around the soda lime canister.

On the expiratory tubing, on the table top, is a blow-off valve which can be set for gas escape at 3, 6, 12 or 38 mm. of mercury pressure. This valve is adjustable by a series of weights.

Four drawers in the cabinet provide for storage of supplies—a spare soda lime canister, wrenches for opening gas cylinders, and a graduated series of weights which can be placed on top of the spirometer (accordion type) bag to exert pressure automatically on inspiration (giving pressures equivalent to 2, 4 and 6 mm. of mercury or combinations thereof). The tubing between unit and mask is the kink-proof type of not less than 2 cm. diameter. The Y piece connecting tubing to the mask has a shunt which allows the patient to breathe air while the mask is being fitted to the face without loss of gases. Two sizes of all rubber masks were submitted with the unit, one labeled "child size" (having a net dead space of 100 cc.) and one labeled "standard size" (having a net dead space of 125 cc. when in position on the face).

Connell Gas Machine, DeLuxe Table Model.

For use with to-and-fro methods of carbon dioxide absorption, a separate coupling and small outlet tube are provided which slip onto the "inspiratory" outlet. To this, the usual to-and-fro mask, canister and bag may be attached. The arrangement of valves makes it unnecessary to plug the "expiratory" outlet.

Resistance to breathing is in the order of 1.6 cm. of water pressure on inspiration and on expiration with the pendant type breathing bag in place. With the spirometer type breathing bag the resistance to expiration is approximately 2 cm. of water pressure, but the weight of the spirometer bag reduces the inspiratory resistance to zero. With the graduated series of weights placed on top of the spirometer bag, the resistance to expiration was shown to be increased by the amount of the weights used and inspiration facilitated by the same amount. The 600 Gm. of soda lime contained in the canister for circuit absorption has a useful life of about six to seven hours before clinical evidence of carbon dioxide excess appears. It must be recognized that carbon dioxide absorption units of either circuit or to-and-fro types in use today do not reduce carbon dioxide in the inspired atmosphere to zero.

Resistance to breathing in the circuit with the pendant type bag is about 35 per cent greater than with Waters' to-and-fro absorption unit. The resistance to expiration with the spirometer bag is 67 per cent greater than with the to-and-fro absorption unit.

In the hands of the skilled anesthetist, the aforementioned gases and their combinations with ether may be efficiently and safely administered, provided the usual precautions known to skilled anesthetists are employed.

A comprehensive booklet of instructions, covering the care of the machine and a description of its mechanics, was submitted. The Council voted to accept the Connell Gas Machine, DeLuxe Model, for inclusion on the Council's list of accepted devices.

**VACOLITE VACUUM TUBE HEARING
AID ACCEPTABLE**

Manufacturer: Vacolite Company, 3003 North Henderson Street, Dallas, Texas.

The Vacolite Vacuum Tube Hearing Aid consists of the following parts:

(a) Combined microphone and vacuum tube amplifier No. 1073, with a control knob on top of the case and an on-and-off contact on the side of the case. The back of the instrument carries a slotted screw for adjusting the frequency response of the instrument. Instruction sheets submitted with the instrument state that setting of this screw changes the response. This unit is enclosed in a molded bakelite case, $3\frac{1}{2}$ by $2\frac{1}{4}$ by $1\frac{1}{4}$ inches, weighing 210 Gm. Control knob and connector plug give maximum dimensions of $4\frac{1}{4}$ by $2\frac{1}{4}$ by $1\frac{1}{4}$ inches.

Vacolite Vacuum Tube Hearing Aid.

(b) A and B batteries incorporated in a single cardboard container holds Vacolite Audio Battery Supply No. 23, containing specially made batteries. Battery replacements can presumably be secured through the manufacturers. Two leads, one from the

A and one from the B battery, are supplied. The battery unit is $4\frac{1}{8}$ by 3 by $1\frac{3}{16}$ inches over all and weighs 327 Gm.

(c) Crystal receiver, $\frac{3}{16}$ inches thick by 1 inch diameter. The instrument was investigated by the Council in an acceptable laboratory. This investigation revealed:

Battery Drain.—The A battery was a single $1\frac{1}{2}$ volt cell drawing on the instrument submitted 70 milliamperes. The B battery voltage was 34 volts and drew 0.70 to 0.80 milliamperes.

Amplification.—The following over-all amplifications at different frequencies were shown with volume control set for full volume:

Frequency	Cycles Per Second					
	128	256	512	1,024	2,048	4,096
At normal ear threshold, frequency control set in extreme counter clockwise position....	nil	?	18	44	38	19 db.
The same, frequency control set at extreme clockwise position	nil	?	10	40	36	19 db.
At approximately 45 decibels above normal threshold frequency control	nil	?	7	20	24	5 db.

Electrical and Mechanical Features.—Electrically the instrument seems to be quite satisfactory. It is quiet and not unduly sensitive to mechanical shocks. It is not subject to feedback squeals with a well fitted earpiece.

The Council on Physical Therapy voted to accept the Vacolite Hearing Aid for inclusion on its list of accepted devices.

**DeVILBISS NO. 147 ELECTRIC STEAM
VAPORIZER ACCEPTABLE**

Manufacturer: The DeVilbiss Company, Toledo, Ohio.

The DeVilbiss No. 147 Electric Steam Vaporizer is used to supply medicated vapor. It is constructed of aluminum, has a flat percolator-type heating unit placed under the water compartment, is mounted on a base plate having thermoplas feet and is insulated to avoid burning the furniture if it boils dry. The unit operates on alternating or direct current, 110-115 volts.

Cotton is placed in a receptacle in the cover of the unit and is saturated with medicament. The firm states that steam is produced in fifteen minutes and that the unit steams one hour and twenty minutes without refilling.

The Council voted to accept the DeVilbiss No. 147 Electric Steam Vaporizer for inclusion on its list of accepted devices.

DeVilbiss No. 147 Electric Steam Vaporizer.

Council on Pharmacy and Chemistry**REPORTS OF THE COUNCIL**

THE COUNCIL HAS AUTHORIZED THE FOLLOWING STATEMENT FOR PUBLICATION. OFFICE OF THE COUNCIL.

ANTIPNEUMOCOCCIC SERUMS

As soon as the evidence submitted seemed to warrant, the Council accepted certain types of antipneumococcic serum; viz., types I, II, IV, V, VII and VIII. These were horse serum preparations. Subsequently the Council accepted the same types of serum as produced in the rabbit.

The remaining generally recognized types of serum have not been accepted by the Council, since adequate volume of clinical data had not been submitted to warrant acceptance, though it was regarded as possible that ultimately most of the other types would be accepted.

At the annual meeting of the Council in March 1940 the situation was again canvassed; as a result it was decided to accept type III antipneumococcic serum (rabbit). The evidence submitted by one manufacturer (Lederle Laboratories, Inc.) indicated that among 91 cases treated with type III rabbit serum there were 18 deaths (20 per cent mortality). There were no strictly comparable control cases, but among 18 cases of type III pneumonia treated without serum there were 11 deaths (61 per cent). The difference in case fatality rates in these series of cases and the evidence presented by clinical members of the Council appeared to warrant the acceptance of type III antipneumococcic serum (rabbit). As evidence accumulates for other types, they will be again considered.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

OFFICE OF THE COUNCIL.

ANTIPNEUMOCOCCIC SERUM, TYPE III (FROM RABBITS).—An antiserum obtained from the blood of an animal of the genus *Lepus*, containing predominantly antibodies to type III pneumococcus (*Diplococcus pneumoniae*).

Dosage.—Average dose, 20,000 to 100,000 units intravenously. The initial and subsequent dosage should be administered in such amount and at such intervals as indicated by the condition of the patient, according to the judgment of the physician. With a large initial dose, fewer units may be curative. The Francis cutaneous test (injection of specific pneumococcic capsular polysaccharide) may be used in conjunction with clinical observations to determine adequacy of dosage.

SODIUM CITRATE 3% W/V SOLUTION-ABBOTT.—A sterile 3 per cent solution of sodium citrate in distilled water contained in a specially adapted bottle which can be equipped with an accompanying rubber bulb attachment to assist the inflow of liquids.

Actions and Uses.—An anticoagulant for indirect blood transfusion and for the preparation of blood plasma. The flow of blood from the needle in the donor's vein into sterile citrate solution of the container is assisted by manipulation of a rubber bulb attachment. The blood is administered to the recipient by gravity flow and is completely filtered.

Dosage.—50 cc. of the solution is used for each 450 cc. of whole blood.

Manufactured by Abbott Laboratories, North Chicago, Ill. No U. S. patent or trademark.

Sodium Citrate 3% W/V Solution-Abbott, 50 cc. in 500 cc. Bottle: Contains 3 per cent sodium citrate in distilled water.

SODIUM CITRATE.—"Contains not less than 10 per cent and not more than 13 per cent of water." U. S. P.

For standards see the U. S. Pharmacopeia under *Sodium Citras*.

SULFAPYRIDINE (See New and Nonofficial Remedies, 1940, p. 494).

The following dosage form has been accepted:

Tablets Sulfapyridine-National Drug Co., 0.5 Gm. (7.7 grains).

Prepared by the National Drug Co., Philadelphia. No U. S. patent or trademark.

in Rome. Kupka and Bennett² report 17 cases, and Weber,³ Schuberth⁴ and Grass⁵ each report a small number of cases. The consensus is uniformly favorable. However, final evaluation is not possible at present. Whether or not the apparent healing of the cavities is permanent must await further observations.

Current Comment

WORK OF THE ROCKEFELLER FOUNDATION IN 1940

Each year the review of the work of the Rockefeller Foundation reflects the progress of endeavor in many fields spread over almost the entire world. The 1940 review presented by the president of the foundation, Raymond B. Fosdick,¹ is tragic in its record of the fate of learning throughout much of the world. The development of the war has forced many scholars into exile, it has forced others to give up their intellectual work, and still others have completely disappeared from sight. The Paris office of the foundation has been closed and the Shanghai office transferred to Manila. The personnel of the foundation has had to be recalled from Egypt, where work was being carried on in malaria and schistosomiasis, and from Turkey, where work in sanitary engineering was being pursued. Likewise the personnel of the foundation had to be removed from Rumania, where scarlet fever studies were being conducted, and from Hungary, which was a station for influenza research. In the face of such developments the foundation has had to reallocate many of its funds. Appropriations have been granted for the establishment and continued work, so far as possible, of eminent refugee scholars; a plan has been initiated and funds have been appropriated for continuation of training in this country of British medical students. Health programs which will be pursued as much as circumstances allow have been initiated by sending a health commission to Europe under the direction of Dr. W. A. Sawyer of the International Health Division. Elsewhere some of the work of the foundation has achieved greater success: progress has occurred in the development of prophylactic measures against influenza; the battle against the *Anopheles gambiae* mosquito in Brazil has made much progress; there have been further developments in unraveling the yellow fever mystery, and the foundation has aided in the establishment of a new school of public health at the University of Michigan. Outside the medical field also the foundation has continued its appropriations and encouragement toward the intellectual life of the world. Its appropriations for 1940 included some transfers from the principal fund of the foundation. Fosdick's report is a moving document which illustrates the attempt of intellectual life to survive under adverse circumstances.

SALT IN HOT INDUSTRIES

The amount of sweat excreted by workers in hot industries is known to be prodigious, at times amounting to several pints an hour. Consumption of water alone to replace abnormal loss of body fluids leads to the condition commonly referred to by miners and furnace workers as "water poisoning." Present day knowledge of water and metabolite balance has demonstrated that the symptoms of heat cramp or heat exhaustion are not the result of overconsumption of water but rather the serious depletion of chlorides. Normally, a man needs a daily intake of from 8 to 15 Gm. of salt to make up for chlorides eliminated in the urine and sweat. In case of excessive perspiration, considerably larger amounts of salt are required to maintain proper balance. The practice of supplying industrial workers with salt, therefore, in hot industries and in hot weather rests on sound physiologic principles. Close observation by many industrial physicians indicates that harmful results need not be expected in otherwise healthy men if there is rough approximation between salt loss and salt replacement. Many industries because of convenience provide salt tablets by dispenser to be taken by the worker with each drink of water. Dextrose is frequently incorporated in the tablet on the assumption that a quick energy source is provided and that it is of value in combating shock associated with heat exhaustion. Actually, blood sugar levels in hot industry workers are not found to be measurably altered.

MATERNAL MORTALITY IN THE SOUTH

Economic causes are fundamentally responsible for high maternal mortality in the South concludes Dr. James R. McCord¹ in his presidential address before the fifty-third annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons. The basis of his remarks was a careful analysis of ninety-seven maternal deaths of Negro women; 37 per cent of the immediate responsibility for these preventable deaths was assigned by him to the hospital doctor, an equal percentage to the patient, 12 per cent to hospital routine, 10 per cent to an outside doctor and only 4 per cent to a midwife. Nearly 60 per cent of the obstetric deaths were from sepsis, but he concludes that "half of these deaths from sepsis were not preventable with the present economic and intellectual environment of the patients." Neglect of this factor has been responsible for much misleading discussion of maternal mortality in the South. Some of the concluding comments of Dr. McCord provide vivid factual support for these conclusions:

"Illiteracy is four times as prevalent in the South as in the rest of the nation. The average expenditure on education per child is about half that of the country as a whole. . . . The South must educate one third of the nation's children with one sixth of the nation's school revenues. . . . The South collects about half as much per person in taxes as does the nation as a whole, but she devotes a larger share of her income to schools. . . . The average farm income in the South is \$186 as compared to \$528 elsewhere. . . . The poorest rural area in America has the greatest number of people. The birth rate of the South exceeds that of any other region."

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

RECREATIONAL CENTERS FOR SOLDIERS

The War Department has selected five more sites for army recreational camps and it plans to extend the program to all training areas when funds are available. Seven recreational camps had previously been established along the Gulf Coast. The sites of the five new camps tentatively selected are at Jacksonville Beach and St. Augustine, Fla., Savannah, Ga., Charleston, S. C., and Wilmington, N. C. The seven original recreational camps or week-end tent cities are at Mobile, Ala., Biloxi, Pascagoula, and Gulfport, Miss., New Orleans, and Panama City and Pensacola, Fla. The present leave-camps are far different from those of World War days. The camps are on sites accessible to downtown areas, and recreation and amusement facilities are available from which the soldier can select or write his own ticket of fun. The purpose of these recreational areas, however, is not only to give the soldier a good time, but it has a definite morale building objective. There are no formations, no roll calls, no reveille. The expenses at the recreational camps are small. Food is obtainable from a concessionaire on the grounds at low cost, and meals in these areas should average from 15 to 30 cents. The civilian populations are extending full hospitality to the soldiers at these camps, and only in case of breach of discipline or where necessary to the interest of the community are the movements of an individual soldier restricted. While the recreational plan is just getting into its stride, facilities are now available to accommodate more than three thousand men weekly at these soldier resorts, and these are to be much increased.

RECOMMENDED DAILY ALLOWANCES FOR SPECIFIC NUTRIENTS

In connection with the preparedness program a subcommittee of the Committee on Food and Nutrition of the National Research Council has prepared the accompanying table of recommended daily allowances for specific nutrients, together

with some appended notes. This may well serve as a guide on specific dietary needs not only for physicians but also for the general public.

EXAMINATIONS FOR NURSES FOR NATIONAL DEFENSE

The U. S. Civil Service Commission announces two new examinations in the medical and nursing fields. Public health nursing consultant positions, paying \$2,600 and \$3,200 a year, are open in the U. S. Public Health Service. Nursing consultants will advise and consult with state health administrators as to the organization and administration of public health nursing within the respective states. They will also assist public health nursing directors in planning staff education programs and in demonstrating the conduct of institutes for groups of nurses. This examination is open only to registered graduate nurses who have finished a four year college course, including or supplemented by one year of study in public health nursing. Applications will not be accepted after July 26.

Applicants will be accepted until further notice for physicians as medical technicians, paying from \$1,620 to \$2,000 a year, and as junior laboratory helper at \$1,440 a year. Persons applying for the full or assistant grade of medical technician may qualify also in surgery. Applicants must have had at least fourteen units of high school study; otherwise they must pass a written general test. Appropriate experience in this field also is required.

The U. S. Civil Service Commission has also reannounced examinations for junior grade nurse at \$1,620. Applicants will not be required to take a test, and the vision requirement has been modified.

Persons interested and qualified for any of these positions should apply to the U. S. Civil Service Commission, Washington, D. C. Application forms may be obtained at any first or second class post office.

These are tentative allowances toward which to aim in planning practical diets. These allowances can be met by a good diet of natural foods; this will also provide other minerals and vitamins, the requirements for which are less well known.

* Requirements may be less than these amounts if provided as vitamin A, greater if chiefly as the provitamin carotene.

† One mg. of thiamine equals 333 international units; 1 mg. of ascorbic acid equals 20 international units (1 international unit equals 1 U. S. P. unit).

‡ Vitamin D is undoubtedly necessary for older children and adults. When not available from sunshine, it should be provided probably up to the minimal amounts recommended for infants.

§ Needs of infants increase from month to month. The amounts given are for approximately 6 to 15 months. The amounts of protein and calcium needed are less if from breast milk.

* Allowances are based on the middle age for each group (as 2.5, 8 and so on) and for moderate activity.

EXAMINATIONS FOR APPOINTMENTS IN MEDICAL CORPS OF NAVY

The next examination for appointments as assistant surgeon, U. S. Navy (lieutenant [junior grade], Medical Corps, U. S. Navy) will be held at all major Medical Department activities on August 11 to 15 inclusive. Applications for this examination must be in the Bureau of Medicine and Surgery not later than July 15.

Applicants for appointment as assistant surgeon must be citizens of the United States, more than 21 but less than 32 years of age at the time of acceptance of appointment, and graduates of a class A medical school who have completed at least one year of intern training in a hospital accredited for intern training by the Council on Medical Education and Hospitals of the American Medical Association.

A circular of information listing physical and other requirements for appointment, subjects in which applicants are examined, application forms and other data pertaining to salary, allowances and so on may be obtained from the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., on request.

An examination for appointment as acting assistant surgeon for intern training in naval hospitals accredited for intern training by the Council on Medical Education and Hospitals will be held at all major Medical Department activities on

June 23 to 26 inclusive. Students in class A medical schools who will complete their medical education this year are eligible to apply for these appointments.

Students in class A medical schools who will have completed their third year of medical education this year are eligible to take this examination and, if successful, will receive their appointments on or about July 1, 1942, after they have completed their medical education.

Applicants for appointment as acting assistant surgeon for intern training must be citizens of the United States, more than 21 but less than 32 years of age at the time of acceptance of appointment. Acting assistant surgeons are appointed for a period of eighteen months. After the appointee has served as an intern in a naval hospital for twelve months he is eligible for and may take the examination for appointment as assistant surgeon, U. S. Navy.

A circular of information listing physical and other requirements for appointment as acting assistant surgeon, subjects in which applicants are examined, application forms and so on may be obtained from the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., on request.

Assistant surgeons and acting assistant surgeons for intern training are appointed in the rank of lieutenant (junior grade), Medical Corps, U. S. Navy. The pay and allowances for an officer of this rank total \$2,699 a year if he has no dependents and \$3,158 a year if he is married or has dependents.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY WAR DEPARTMENT

The following additional medical reserve corps officers have been ordered to extended active duty by the War Department, Washington, D. C.:

ABRAMS, Edward William, 1st Lieut., Portland, Ore.
ALBRITTON, Andrew Stirling, 1st Lieut., New Orleans.
BERG, Richard Fredrick, Captain, Portland, Ore.
BOYLSTON, George Arthur, 1st Lieut., Wilmette, Ill.
CHAMBERLIN, Donald Tillinghast, Captain, Boston.
CHENEY, William Swartz, 1st Lieut., Baltimore.
COOPER, Harold John, Captain, Fresno, Calif.
DERRIG, Raymond Edwin, 1st Lieut., Washington, D. C.
EBERHARD, Theodore Philip, 1st Lieut., Columbia, Mo.
EIGENBROD, Frederick August, 1st Lieut., New Orleans.
GOTTLIEB, Jacob Daniel, Captain, Talmage, Calif.
GRIFFIN, Lawrence Lafayette, 1st Lieut., Galveston, Texas.
HAYNES, Walter George, 1st Lieut., Chicago.
HEALY, Martin Joseph, Jr., 1st Lieut., New York.
HEWITT, Perry Edwin, Jr., 1st Lieut., Muskogee, Okla.
HOLOUBEK, Joe Edward, 1st Lieut., New Orleans.
HORN, Leonard, 1st Lieut., Rochester, N. Y.

JAMES, Alfred Elmore, 1st Lieut., Beavertown, Pa.
KELLOGG, Frederick, Captain, Long Beach, Calif.
McCULLOUGH, John Davis, 1st Lieut., East Knoxville, Tenn.
MINNETT, John Sables, Captain, Dallas, Texas.
MIRA, Anthony Agathon, 1st Lieut., Corona, N. Y.
NELSON, Donald C., Captain, Fort Defiance, Ariz.
PODESTA, Joseph John, 1st Lieut., Cincinnati.
SCHULTZ, Abraham, 1st Lieut., Chicago.
SNYDER, Rufus Adam, 1st Lieut., Chicago.
SPELLBERG, Mitchell Abraham, 1st Lieut., Chicago.
STOLAR, Robert, 1st Lieut., Washington, D. C.
SULLIVAN, Clement Joseph, Captain, St. Louis.
VORISEK, Elmer Albert, 1st Lieut., Oak Park, Ill.
WALLACE, Joseph James, 1st Lieut., Washington, D. C.

Orders Revoked

HILL, Thurman K., 1st Lieut., Nashville, Tenn.
JONES, Harry D., 1st Lieut., Nashville, Tenn.
KOLCZUN, Michael C., 1st Lieut., New Orleans, La.
LUTHER, Ross Daniel, 1st Lieut., Denver.
MORGAN, Edward S., 1st Lieut., Pendleton, Ore.

THIRD CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Third Corps Area, which comprises the states of Pennsylvania, Virginia, District of Columbia and Maryland:

BAILEY, William Otis, Jr., 1st Lieut., Leesburg, Va., Fort George G. Meade, Md.
BARNES, Earl Bower, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
BEERMAN, Curtis Arthur, 1st Lieut., Altoona, Pa., Fort George G. Meade, Md.
BENZON, George Henry III, 1st Lieut., Jenkintown, Pa., Fort George G. Meade, Md.
BIGLEY, Joseph Robert, 1st Lieut., Philadelphia, Fort George G. Meade, Md.
BRINDISI, Gaetano, 1st Lieut., Philadelphia, Fort George G. Meade, Md.
BURGESS, Forbes Hathaway, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
CALL, Manfred III, 1st Lieut., Richmond, Va., Fort George G. Meade, Md.
CANTOR, Paul David, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
CHESTNUT, John Letcher, 1st Lieut., Mountain Grove, Va., Fort George G. Meade, Md.
DODD, William Anthony, 1st Lieut., Baltimore, Fort George G. Meade, Md.
FARNSWORTH, David Ivan, 1st Lieut., Richmond, Va., Fort George G. Meade, Md.
FIORE, Charles Nicholas, 1st Lieut., Brentwood, Md., Fort George G. Meade, Md.

FLOCKS, Milton, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
HANNA, Michael Ignatius, 1st Lieut., Covington, Va., Fort George G. Meade, Md.
HEIGES, Harold Lynwood, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
HEIMOFF, Leonard Lincoln, 1st Lieut., Baltimore, Fort George G. Meade, Md.
HIGHSTEIN, Benjamin, 1st Lieut., Baltimore, Fort George G. Meade, Md.
KRAMM, August Herman, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
MARTIN, Carroll James, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
McCONNELL, Frederick Gray, 1st Lieut., Gate City, Scott County, Va., Camp Davis, N. C.
McMAHON, John Martin, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
NELMS, Nowell Darden, 1st Lieut., Mathews, Va., Fort George G. Meade, Md.
O'BRIEN, James Nester, 1st Lieut., Harrisburg, Pa., Fort George G. Meade, Md.
PROKOP, Albert George, 1st Lieut., Clairton, Pa., Fort George G. Meade, Md.
RATCLIFFE, Harold Elton, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
SNOW, Lee Bruner, 1st Lieut., Washington, D. C., Fort George G. Meade, Md.
STEHRMAN, Vernon Andrew, 1st Lieut., Arlington, Va., Fort George G. Meade, Md.
VARNER, Winter Thomas, 1st Lieut., Richmond, Va., Fort George G. Meade, Md.
WALKE, John Talb, 1st Lieut., Norfolk, Va., Fort George G. Meade, Md.

WARE, Robert Barnes, 1st Lieut., Lynchburg, Va., Fort George G. Meade, Md.
WILKINS, Jesse Lee, 1st Lieut., Pocomoke City, Md., Fort George G. Meade, Md.
WILLIAMS, Ben Clayton, 1st Lieut., Baltimore, Fort George G. Meade, Md.
TURNER, Phillip Rorison, 1st Lieut., Takoma Park, Md., Fort George G. Meade, Md.

Orders Revoked

AXELMAN, Edward Lewis, 1st Lieut., Darby, Pa.
BAUSCHER, Abner H., Lieut. Col., Reading, Pa.
BOSS, Myron Theodore, 1st Lieut., Baltimore.
CORLEY, Karl C., 1st Lieut., Chevy Chase, Md.
DAPARMA, Frank L., 1st Lieut., Pittsburgh.
DEAN, James S., Captain, Spring City, Pa.
DEGNAN, Philip A., 1st Lieut., Washington, D. C.
DOUGLAS, Harry S., 1st Lieut., Washington, D. C.
ECKHARDT, John C., Lieut. Col., Washington, D. C.

SIXTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Sixth Corps Area, which comprises the states of Wisconsin, Illinois and Michigan:

ADELSON, Sidney L., 1st Lieut., Detroit, Selfridge Field, Mount Clemens, Mich.
ALLISON, Olaf W., 1st Lieut., Danville, Ill., 27th Division, Fort McClellan, Ala.
ANDERSON, Donald H., 1st Lieut., Greenville, Ill., 27th Division, Fort McClellan, Ala.
ANDERSON, William H., 1st Lieut., San Francisco, Air Corps Basic Flying School, San Angelo, Texas.
BERRY, Robert E. L., 1st Lieut., Detroit, 12th Station Hospital, Camp Forrest, Tenn.
BOWEN, Robert E., 1st Lieut., Chicago, 27th Division, Fort McClellan, Ala.
BOWERS, Paul A., 1st Lieut., Chicago, Air Base, Tucson, Ariz.
BROCK, Clayton E., 1st Lieut., St. Louis, Station Complement, Camp Shelby, Miss.
BUCKLEY, Clarence H., Captain, Menomonie, Wis., 10th Station Hospital, Camp Claiborne, La.
CARR, James G., Major, Detroit, 12th Station Hospital, Camp Forrest, Tenn.
COSTIN, Max, 1st Lieut., Chicago, Air Base, Tucson, Ariz.
CRAMER, Oliver S., 1st Lieut., Detroit, Selfridge Field, Mich.
CRISMON, Lester C., 1st Lieut., Chicago, 32d Division, Camp Beauregard, La.
CULMER, Charles U., 1st Lieut., Iowa City, Air Base, Oklahoma City.
DIAMONDSTONE, Albert H., 1st Lieut., Chicago, Station Complement, Camp Shelby, Miss.
DILLON, Walter F., 1st Lieut., St. Louis, Station Complement, Camp Shelby, Miss.
EHLERT, Charles D., Captain, Alton, Ill., Scott Field, Ill.
FADEN, Gerson, 1st Lieut., Moweaqua, Ill., Randolph Field, Texas.
HAVRANEK, James C., 1st Lieut., Cicero, Ill., Chanute Field, Rantoul, Ill.
JANCI, Julius S., 1st Lieut., Owosso, Mich., Station Complement, Camp Croft, S. C.
JEDLIKA, Frank L., 1st Lieut., Cicero, Ill., Station Hospital, Fort Sill, Okla.
KACZKOWSKI, Joseph C., Major, Chicago, 9th Station Hospital, Fort McClellan, Ala.
KASABACH, Harry Y., 1st Lieut., Chicago, Station Complement, Camp Croft, S. C.
KAYE, Raymond J., 1st Lieut., Palmyra, Mich., Station Complement, Camp Wheeler, Macon, Ga.
KESERT, Meyer, 1st Lieut., Chicago, Chanute Field, Rantoul, Ill.
KIRK, Max Lee, 1st Lieut., Mount Vernon, Ill., 27th Division, Fort McClellan, Ala.
KUDOLLA, Charles R., 1st Lieut., Chicago, Station Complement, Camp Polk, La.
LARRABEE, Walter F., Jr., Chippewa Falls, Wis., Station Complement, Camp Wheeler, Macon, Ga.
LEVAN, Arthur B., 1st Lieut., Chicago, Station Complement, Camp Polk, La.
LURIE, Robert I., 1st Lieut., Saginaw, Mich., Station Hospital, Fort Bliss, Texas.
MAIBAUER, Frederick P., 1st Lieut., Wyandotte, Mich., Air Base, Oklahoma City.

EINHORN, Nathan Harry, 1st Lieut., Philadelphia.
FOCHT, William W., 1st Lieut., Lebanon, Pa.
HARMEIER, John Watson, Captain, Pittsburgh.
HOFFSTEIN, Louis D., 1st Lieut., Philadelphia.
HULBURT, Richard Stephen, 1st Lieut., Washington, D. C.
HUNTER, OSCAR BENWOOD, Major, Washington, D. C.
JONES, Clement Russell, Jr., Captain, Dixmont, Pa.
KELLY, Edward A., 1st Lieut., Washington, D. C.
MAINZER, Francis S., Major, Huntingdon, Pa.
MILLER, Cledith Aten, 1st Lieut., Wilkes-Barre, Pa.
MILLER, Harry Archer, Captain, Baltimore.
MINTEER, James W., Captain, Ridgway, Pa.
O'BOYLE, James Patrick, 1st Lieut., Dunmore, Pa.
ROBBINS, Leo E., 1st Lieut., Philadelphia.
SHUBIN, Harry, 1st Lieut., Philadelphia.
SILVER, Israel Oscar, 1st Lieut., Steelton, Pa.
TOMPKINS, Pendleton Souther, Captain, Philadelphia.
URIDEL, Frank Arthur, 1st Lieut., Newfoundland, Pa.
WEBER, George Samuel, 1st Lieut., Waldorf, Md.

MARTIN, Forrest R., 1st Lieut., Decatur, Ill., Chanute Field, Rantoul, Ill.
MATHEI, Louis P., 1st Lieut., South Wayne, Wis., U. S. Army Induction Station, Milwaukee.
MATZKIN, Lloyd L., 1st Lieut., Chicago, Station Complement, Fort Jackson, S. C.
McALLISTER, Ralph G., Captain, DeKalb, Ill., 33d Division, Camp Forrest, Tenn.
McNERTNEY, Francis D., Major, Bloomington, Ill., 5th Station Hospital, Camp Stewart, Ga.
MILLER, Edward B., 1st Lieut., Chicago, Station Complement, Camp Polk, La.
MILLS, Morton J., Captain, Chicago, U. S. Army Induction Station, Chicago.
MULROONEY, Raymond E., 1st Lieut., Litchfield, Ill., Station Complement, Camp Polk, La.
OLSON, James A., 1st Lieut., Flint, Mich., Selfridge Field, Mount Clemens, Mich.
PRUSINSKI, Jerome C., 1st Lieut., Chicago, Station Complement, Fort Jackson, S. C.
RAU, Frederick W., 1st Lieut., Saginaw, Mich., 24th Infantry, Fort Benning, Ga.
REINARDY, Everett W., 1st Lieut., Burlington, Wis., Station Complement, Camp Wheeler, Macon, Ga.
SCHICK, William R., 1st Lieut., Chicago, Air Base, Albuquerque, N. M.
SCHROEDER, Charles M., 1st Lieut., Camp Grant, Ill., Station Complement, Fort Custer, Mich.
SCHUMAN, Irving, 1st Lieut., Chicago, Chanute Field, Rantoul, Ill.
SCHUTZ, William J., 1st Lieut., Munising, Mich., Selfridge Field, Mount Clemens, Mich.
SILVERSTEIN, Joseph, 1st Lieut., Chicago, Station Complement, Chanute Field, Ill.
SPINKA, Isadore, 1st Lieut., Chicago, Station Complement, Camp Wheeler, Macon, Ga.
SPRINGER, Eugene W., 1st Lieut., Iowa City, Air Base, Oklahoma City.
SWANSON, George F., Captain, Newberry, Mich., 9th Station Hospital, Fort McClellan, Ala.
SWENSON, Leland L., 1st Lieut., Grand Rapids, Mich., 27th Division, Fort McClellan, Ala.
STOTZ, Kenneth F., 1st Lieut., Chicago, 33d Division, Camp Forrest, Tenn.
TUROW, Irving L., 1st Lieut., Peoria, Ill., Station Hospital, Fort Custer, Mich.
VAN NOORD, Gelmer A., 1st Lieut., Grand Rapids, Mich., 27th Division, Fort McClellan, Ala.
WEDRAL, Jerry W., 1st Lieut., Cicero, Ill., 27th Division, Fort McClellan, Ala.
WESCOTT, Royal J., 1st Lieut., Marquette, Mich., 11th Station Hospital, Fort Custer, Mich.
ZLATKIN, Louis, 1st Lieut., Detroit, Selfridge Field, Mount Clemens, Mich.

Orders Revoked

BASSUENER, Reynold O., Captain, Warren, Wis.
HIRSCHFELD, Alexander H., 1st Lieut., Ann Arbor, Mich.
HUBBLE, William Fields, Jr., 1st Lieut., Decatur, Ill.
PAISLEY, Alfred M., 1st Lieut., Jacksonville, Ill.
PRUDOWSKY, Harry H., 1st Lieut., Milwaukee, Wis.
ST. PIERRE, Roderick G., Captain, Portland, Ore.
WEICHSELBAUM, Paul K., 1st Lieut., Chicago.

ARMY VACANCIES FOR DIETITIANS

Approximately three hundred and fifty vacancies for dietitians exist in army hospitals, which now have one hundred and three dietitians on duty. A school for dietitians is conducted at the Army Medical Center, Washington, D. C. Since the requirements for entrance include graduation from a recognized college with a major course in dietetics and nutrition, the course is devoted mainly to procedure peculiar to the military service. The pay of dietitians is \$1,800 a year. In time of peace only female dietitians certified by the Civil Service Commission are employed in Army hospitals. In time of war, however, men

qualified as dietitians will be enlisted as technical sergeants as far as vacancies exist.

NAVY ASSIGNMENTS NOT TO BE PUBLISHED

A recent order from the Secretary of the Navy restricts from general publication nomination of all officers of the Navy. Therefore, lists of the names of the United States Naval Reserve Officers reporting for active duty in the Navy, with the names of the stations to which they have been assigned, as published previously, will not be continued.

ORGANIZATION SECTION

OFFICIAL NOTES

JUDGE PROCTOR IMPOSES SENTENCE

Following the trial of the U. S. Government versus the American Medical Association and other defendants on charges of violating the Sherman Anti-Trust Act and their conviction by a jury April 4, Justice James M. Proctor of the District Court in Washington, D. C., on May 29, imposed a fine of \$2,500 on the Association and a fine of \$1,500 on the Medical Society of the District of Columbia. The defense counsel announced that an appeal to the higher courts would be filed. The proceedings of the trial were published in various issues of THE JOURNAL beginning February 15.

ADDRESSES BY OFFICIAL STAFF

DR. W. W. BAUER:

June 20—University of New Hampshire, Durham.

DR. MORRIS FISHBEIN:

June 17—Institute of Food Technologists, Pittsburgh.

June 26—Iowa and Illinois Central District Medical Association, Davenport, Iowa.

DR. FRANK H. LAHEY:

June 9—Massachusetts Institute of Technology, Cambridge.

June 11—Testimonial dinner to Dr. Fred Hussey, Providence, R. I.

June 24—Maine Medical Association, York Harbor.

DR. CARL M. PETERSON:

June 14—Utah State Medical Association, Salt Lake City.

June 19—Twin Lakes District Medical Society, Rockwell City, Iowa.

June 20—National Association of Manufacturers and the Associated Industries of Alabama, Birmingham.

DR. PAUL A. TESCHNER:

June 10—Friends of Rural Public Health Nursing, Norwood Park Township, Chicago.

MEDICAL ECONOMIC ABSTRACTS

SOCIAL SECURITY AND SICKNESS INSURANCE

The "Fifth Annual Report of the Social Security Board, 1940" contains several paragraphs directly or indirectly advocating the extension of social security legislation to cover the loss due to sickness. Pages 15 and 16 of the report say:

There is one major risk to economic security for which there is yet no provision in the social security program and only inadequate provision under other legislation—the risk of medical costs and of wage loss during illness or during temporary or permanent disability. In his capacity as a member of the Interdepartmental Committee to Coordinate Health and Welfare Activities, the chairman of the board has shared in the report and recommendations transmitted by that body to the President and the Congress. The board wishes to reiterate its endorsement of the goals and principles proposed in that report on a national health program.

Provisions to prevent sickness and maintain health and earning power and to offset the wage losses occasioned by disability are of direct moment to the programs already in operation. The present unemployment compensation laws and the funds they provide are designed to safeguard unemployed wage earners who are available for jobs. Yet there is obvious injustice in giving benefits to such workers and denying them to a worker who is out of a job because he is sick even though he may have had an identical record of past covered employment and may be suffering the same wage loss. It is impossible to face with equanimity the situation in the home of a worker who is insured under the federal old age and survivors' insurance system when he becomes sick or disabled but dies after a period of disability during which his insured status has lapsed. If he had died before the end of that period, benefits which ordinarily are substantial in amount would have been payable to his children throughout their childhood and to his widow while she had such children in her care. With long-continued illness, however, in which costs of medical care are commonly beyond the resources of families of small means, there will often be a loss of these insurance rights and, in most such cases, a total loss of provision for the survivors. . . .

The board trusts that the Congress will be able to give early attention to the various measures that have been proposed for

safeguarding the health of the American people and averting or offsetting the economic distress caused by sickness and disability.

In the discussion of medical and institutional care (pages 100-101) the report says:

The inadequacy of provisions for the medical care of recipients of public assistance has continued to be one of the major problems confronting the state agencies and their local units. Increasing attention has been given to possible methods of meeting this need. During the fiscal year the board's consultants on medical problems and on medical social work visited sixteen states in which the state agencies had requested advice on specific problems in this field.

It is noted that:

Several states have suggested that the needs of recipients could be met more adequately if the federal government were willing to participate financially in payments to recipients for medical purposes.

However, the report concludes that

at least three major difficulties are present in attempting to meet the medical expenses of recipients of public assistance through regular allowances in the assistance payment. In the first place, it is obviously impossible to develop proper community medical facilities through the small additional amounts which might be included in the assistance plans made with recipients of public assistance, though in states and localities in which facilities are available for such services the inclusion of such allowances in the regular payments will permit wider and more effective use. In the second place, many types of medical needs are not predictable, and the expenses necessarily incurred may be of such magnitude that they must be met out of a special payment rather than through inclusion of an additional amount in the monthly public assistance payment. The third problem, which is of more fundamental significance, concerns the question whether the development of a program of medical care in connection with the three assistance programs under the Social Security Act would assist or hamper the development of a broader program of medical care for those groups in our population who are not now able to obtain needed services.

The Bureau of Research and Statistics of the board has undertaken health and disability studies concerning which the report says (page 140):

Studies of illness and disability as a cause of economic insecurity were continued during the year, and consideration was given to proposals for extending the social security system to include the risk of ill health and disability. Basic data were compiled and cost estimates were prepared for specific legislative programs under consideration by the Congress, and work was continued on the formulation of alternative specifications to be considered in the adoption of a program. Extensive analyses were made of American and foreign experience in order to provide a basis for estimating the extent and frequency of temporary and permanent disability to be anticipated under specified disability insurance programs. These studies have also included detailed analyses of the wage records of the old age and survivors' insurance program, in order to estimate the number of individuals with fully and currently insured status in future years.

Information has been collected concerning federal and state legislative proposals to provide medical services for various segments of the population. These proposals have been analyzed especially in their relationship to existing social insurance systems. Investigations of the extent and character of unmet medical needs have included studies of the receipt of medical services by urban and rural families in different income groups and expenditures by these groups for various types of medical services. On the basis of monthly reports submitted voluntarily by selected organizations, special studies are being undertaken to determine the volume and type of medical care furnished

under prepayment medical service plans and the personnel required for the operation of such plans. Consideration has been given to the analysis of methods for providing more nearly adequate medical care, especially through social insurance.

REFERENDUM ON INSURANCE

A recent referendum on voluntary sickness insurance conducted by the West Virginia State Medical Association showed that 71 per cent favored some plan of voluntary sickness insurance, 28 per cent were against it and 1 per cent returned their ballots with comments but without voting. The vote is primarily 4 to 1 in favor of limiting coverage to the low income group. According to the *West Virginia Medical Journal* (37: 226 [May] 1941) it is expected that a proposal for some type of prepayment plan to be operated by the West Virginia State Medical Association will be considered at the next meeting of the house of delegates.

HEALTH IN CANADA

The statisticians of the Metropolitan Life Insurance Company find that in spite of the war the Canadian death rate for 1940 among that company's Canadian industrial policyholders was 12.1 per cent lower than the average rate for the preceding five years and that the rate declined for practically every age among both men and women. The tuberculosis rate dropped 15 per cent as compared with the rate in the preceding five years. Violent deaths were also less in 1940 than in other recent years.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status.—H. R. 4476 has been reported to the House, providing for sundry matters affecting the Military Establishment. As introduced, this bill provided, among other things, for the employment of interns in the Medical Department of the Army at not to exceed \$720 per annum. As reported, the bill would authorize the Secretary of War "to provide for the employment of interns who are graduates of or have successfully completed at least four years' professional training in reputable schools of medicine or osteopathy in the Medical Department, at not to exceed \$720 per annum."

Bill Introduced.—On May 14, the President requested additional funds for emergency and sanitation work of the United States Public Health Service, in the amount of \$1,235,000.

STATE MEDICAL LEGISLATION

Florida

Bills Introduced.—S. 649 and H. 961 propose to enact a separate massage and physical therapy practice act and to create a board of massage and physical therapy examiners to examine and license applicants for licenses to practice massage and physical therapy. Section 8 of both bills reads as follows: "Massage and Physiotherapy Defined. For the purpose of this Act, massage is defined as follows: The Act of scientifically rubbing or kneading the soft superficial structures of the human body for the purpose of stimulating or restoring normalcy of circulation and tonicity of such structures, and for the relief of pain. In no way shall this Act interfere with the practice of osteopathy, chiropractic, or naturopathy, as is now governed by law. Applicant must, however, have elementary knowledge of anatomy, physiology and electrotherapeutics." H. 1416 proposes to enact a separate massage practice act and to create an independent state board of massage to examine and license applicants for licenses to practice massage. The bill provides that "the practice of massage is hereby declared a profession, and for the purpose of this Act is hereby defined as follows,

viz.: The scientific manual manipulation of the tissue and muscles of the human body, together with the skilful use of scientific apparatus usually associated with the practice of massage in administering such treatments as cabinet baths, turkish baths, reducing treatments, fomentations, natural and artificial heliotherapy, vibratory treatments and colonic-irrigations."

Bill Passed.—H. 1337 passed the House May 19, proposing to authorize the Board of County Commissioners of Clay County to levy on all taxable property an additional tax of two mills to care for the indigent inhabitants of that county who are in need of hospitalization and medical care.

Illinois

Bills Introduced.—H. 866 proposes to enact what it cites as the Illinois Food, Drug and Cosmetic Act to regulate the manufacture, sale, distribution and advertising of foods, drugs, cosmetics and therapeutic devices. H. 896 proposes to require each county to provide funds for the treatment of indigent persons afflicted with cancer or tumor.

Massachusetts

Bill Introduced.—H. 2528 proposes to prohibit the operation of a hospital or sanatorium unless licensed to do so by the state department of health.

Michigan

Bill Introduced.—H. 580 proposes to authorize the state council of health to establish and maintain a bureau of cancer control in the state department of health. The proposed bureau is to be authorized to promote measures to reduce the mortality from cancer by programs of education and by provision for necessary diagnostic laboratory work for persons financially unable to pay for the same. The proposed work of the bureau is not to be limited to public laboratories, but private laboratory facilities may be fully employed in those areas in which they are adequate and available.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

State Medical Election.—Dr. James M. Mason, Birmingham, was elected president of the Medical Association of the State of Alabama at its meeting in Mobile in April, succeeding Dr. Samuel A. Gordon, Marion. Dr. John Paul Jones, Camden, whose term as vice president expired this year, was reelected for another four year term. Others now serving as vice presidents are Drs. Roscoe C. Stewart, Sylacauga; John S. Tillman, Clio, and Merle E. Smith, Parrish. Montgomery was chosen as the place for the 1942 meeting.

ARKANSAS

Personal.—Dr. Herbert H. McAdams has been elected president of the Jonesboro School Board and Dr. Walter C. Overstreet, vice president.—Dr. Leroy L. Fatherree has been chosen health officer of Little Rock.

State Medical Election.—Dr. Rufus B. Robins, Camden, was chosen president-elect of the Arkansas Medical Society at its recent annual meeting in Little Rock and Dr. Herbert Fay H. Jones, Little Rock, was inducted into the presidency, succeeding Dr. Henry T. Smith, McGehee. Other officers include Drs. Henry King Wade, Hot Springs National Park; Carl C. Hanchey, DeQueen, and Bonny N. Stevenson, West Memphis, vice presidents; Royal J. Calcote, Little Rock, treasurer, and William R. Brooksher, Fort Smith, secretary.

CALIFORNIA

State Medical Election.—Dr. William R. Molony Sr., Los Angeles, was chosen president-elect of the California Medical Association at its annual meeting in May in Del Monte and Dr. Henry S. Rogers, Petaluma, was installed as president. Del Monte was again chosen as the place for the 1942 meeting, probably the first week in May.

Portrait of Dr. Frank Lynch.—A portrait of Dr. Frank W. Lynch, professor of obstetrics and gynecology, University of California Medical School, San Francisco, now hangs in the University Hospital, the gift of friends and students of Dr. Lynch. The gift commemorates his twenty-five years as professor in the medical school. The presentation was made by Dr. Ludwig A. Emge, clinical professor of obstetrics and gynecology at Stanford University School of Medicine, San Francisco, Dr. Lynch's first resident at California. Dr. Lynch was born in Cleveland on Nov. 5, 1871 and graduated at Johns Hopkins University School of Medicine, Baltimore, in 1899. He served on the staff of his alma mater from 1900 to 1904, at Rush Medical College, Chicago, 1905 to 1915, when he went to California. He was a member of the editorial boards of *Surgery, Gynecology and Obstetrics*, the *American Journal of Obstetrics and Gynecology* and the *Western Journal of Surgery*. He served as a member of the advisory board of the committee on prenatal and maternal care of the White House Conference and in 1936 was honor guest of the Pan-Pacific Surgical Congress. He was chairman of the Section on Obstetrics and Gynecology and Abdominal Surgery of the American Medical Association, 1923-1924.

DISTRICT OF COLUMBIA

Medical Society Election.—Dr. Andrew Magruder MacDonald, coroner in the District, has been chosen president-elect of the Medical Society of the District of Columbia. He will take office in 1942. Dr. Henry R. Schreiber, now president-elect, will succeed Dr. Daniel L. Borden as president in July. Other newly elected officers include Drs. J. Lawn Thompson Jr. and Grace G. Pursa, vice presidents.

ILLINOIS

Courses in Obstetrics and Pediatrics.—The University of Illinois College of Medicine, Chicago, announces a series of continuation study courses in obstetrics and pediatrics at Research and Educational Hospital, Chicago, in cooperation with the state department of public health, the state medical society and the approved medical schools of Chicago. The course of study will be repeated at weekly intervals June 16, 23, July 7, 14. Instructors representing Rush Medical College

will be Drs. Joseph L. Baer and Arthur H. Parmelee; Illinois medical school, Drs. William H. Browne, Frederick H. Falls, Julius H. Hess, Bengt L. K. Hamilton, Alfred J. Kobak, Charles Newberger, Henry G. Poncher, Harry Leichenger; University of Chicago, The School of Medicine, Douglas N. Buchanan, Henry C. Hesseltine, William J. Dieckmann; Northwestern University Medical School, William C. Danforth, John A. Bigler, Stanley Gibson, and Loyola University School of Medicine, Dr. Herbert E. Schmitz. One lecture will be given each morning and the remainder of the day will be given over to informal conferences in the dispensaries at the Research Hospital, ward walks at both Cook County and Research hospitals, special demonstrations of technics, round table discussions, manikin work and other special activities.

CHICAGO

Courses in Obstetrics.—The Illinois State Department of Public Health and the U. S. Children's Bureau are sponsoring ten four week courses in obstetrics during 1941-1942 at the Chicago Lying-in Hospital, University of Chicago, beginning June 30. Only a limited number of physicians will be accepted for each course. Members of the university staff will participate in the courses, which include lectures, clinics and birth room demonstrations. Application and inquiries should be addressed to Postgraduate Course, Department of Obstetrics and Gynecology, 5848 Drexel Avenue.

New Appointments in Psychiatry at Illinois.—Dr. Francis J. Gerty, clinical professor and chairman of the department of neurology and psychiatry, Loyola University School of Medicine, has been appointed professor and head of the department of psychiatry at the University of Illinois College of Medicine, filling the vacancy brought about by the death of Dr. Harold Douglas Singer last August. This appointment was effective June 1. Dr. Paul L. Schroeder, professor and head of the department of criminology, social hygiene and medical jurisprudence at the university, will become professor of psychiatry, September 1. Dr. Schroeder will also be in charge of child psychiatry and of the children's ward in the Neuropsychiatric Institute at the school. Dr. Gerty was born in Chicago in 1892, graduating at Loyola in 1921. He taught in the Chicago public schools from 1912 to 1916 and since 1922 has been superintendent of Cook County Psychopathic Hospital and county physician. He was associate professor of nervous and mental diseases at Loyola from 1926 to 1930, when he was named professor and head of the department. Born in Hoytton, Ill., in 1894, Dr. Schroeder graduated at Illinois in 1919. He was neuropsychiatrist with the U. S. Veterans Bureau from 1921 to 1922; assistant managing officer and acting managing officer at the Lincoln State School and Colony, 1922-1924, and psychiatrist, division of criminology, state department of public welfare, 1924-1930. He has been state criminologist, director of the Institute for Juvenile Research and professor and head of the department of criminology at Illinois since 1931. In 1940 he was president of the American Orthopsychiatric Association.

KANSAS

Postgraduate Clinics.—The University of Kansas School of Medicine, Lawrence-Kansas City, conducted its tenth annual postgraduate clinics, April 7-10. This year emphasis was placed on diagnostic and therapeutic procedures. The session concluded with a symposium on sulfonamide drugs, presented by Drs. Ralph H. Major, Leroy A. Calkins, Nelse F. Ockerblad, James B. Weaver, all of Kansas City, Mo., and Tom R. Hamilton, Kansas City.

The Porter Lectures.—Dr. Frederick A. Collier, professor of surgery, University of Michigan Medical School, Ann Arbor, delivered the eleventh course of lectures under the Porter Lectureship in Medicine of the University of Kansas School of Medicine, Lawrence-Kansas City, May 20-21. His subjects were "The Role of Fascia in the Spread of Infection," "The Historical Relation of Medicine and Surgery" and "Treatment of Wounds with Special Reference to Those Produced by War."

KENTUCKY

Personal.—Dr. John Henry Rompf, clinical director of the Eastern State Hospital, Lexington, has been called to military service and Dr. Anthony E. Coletti, formerly of Norfolk, Neb., has succeeded him at the hospital.—Dr. Emil A. Steiner, Somerset, has resigned as health officer of Pulaski County.—Dr. Lee A. Dare, formerly of Lawrenceburg, has resigned as health officer of Anderson County, and Dr. Paul D. Moore, Calhoun, has resigned in McLean County.

MEDICAL NEWS

260.

Dr. Gary Heads State Association.—Dr. William E. Gary, Hopkinsville, has been named president of the Kentucky State Medical Association to fill the unexpired term of the late Dr. Austin Bell, Hopkinsville. Dr. Bell died suddenly in Louisville, April 3. Dr. Gary will serve until the annual meeting of the association, September 29-October 2, when Dr. Elmer L. Henderson, Louisville, will become president.

Society News.—A symposium on military medicine was presented before the Jefferson County Medical Society, Louisville, May 19, by Lieut. Col. Claude D. Holmes, M. C., U. S. Army, Fort Knox, on "Surgical Problems of Army Service"; Lieut. Col. Alvin J. Bayley, M. C., U. S. Army, Fort Knox, on "Prevention and Treatment of Acute Respiratory Disease at Fort Knox, Winter of 1940-1941"; Major William N. Lipscomb, Louisville, "Medical Phases of Selective Service," and Capt. Gus W. Neece, flight surgeon, Patterson Field, Fairfield, Ohio, "Aviation Medicine."—Drs. David Woolfolk Fayette County Medical Society in Lexington, addressed the "Treatment of Peripheral Vascular Disease" and "Bladder Symptoms with Normal or Apparently Normal Urine in the Female" respectively.

MASSACHUSETTS

Dr. Beecher Made Professor.—Dr. Henry K. Beecher, associate in anesthesia at Harvard Medical School, Boston, has been appointed professor to fill the Dr. Henry Isiah Dorr Chair of Research and Teaching in Anesthetics and Anesthesia at the school. Dr. Beecher graduated at Harvard in 1932.

Course in Public Health Engineering.—The department of biology and public health, Massachusetts Institute of Technology, Cambridge, announces a summer course in public health engineering, June 16-July 25. Subjects to be covered are civil and military sanitation, sanitary bacteriology, sanitary biology and sanitary chemistry. For further information write to Murray P. Horwood, Ph.D., Room 10-439, Massachusetts Institute of Technology, Cambridge.

District Society Observes One Hundredth Anniversary.—The Essex North District Medical Society celebrated its one hundredth anniversary in Lawrence, May 7. The program included an inspection of the city's hospitals and a visit to various textile plants. The annual dinner was addressed by Drs. Walter G. Phippen, Salem, president of the Massachusetts Medical Society, and Frank H. Lahey, Boston, President-Elect of the American Medical Association. Three dramatizations of important medical events that occurred within the past hundred years were presented by members of the society, under the direction of Dr. Benjamin Spector, professor of anatomy and medical history, Tufts College Medical School, Boston. Old photographs, instruments and manuscripts of historical significance pertinent to the hundred years' existence of the society were on display. A ladies' program was also held to commemorate the anniversary.

MINNESOTA

Duluth's First Citizen for 1940.—Dr. William R. Bagley, who has been practicing medicine in Duluth for forty-three years, has been selected as the city's "first citizen" for 1940, it was announced at the seventeenth annual "Hall of Fame" dinner, March 29. Dr. Bagley was presented with an American Legion plaque emblematic of his membership in Duluth's "immortal body," and his picture will be placed in the Hall of Fame corridor in the city hall. This idea was conceived by the David Wisted post of the Legion in Duluth in 1925. The choice of Dr. Bagley for this honor was made by the presidents of the eighteen leading civic and community clubs and women's organizations for "his work last year in the Duluth, state and national Izaak Walton leagues (for high school students), for his service as a member of the board of directors of the Chamber of Commerce and for his community leadership as president of the Rotary Club." He graduated at the University of Michigan Medical School, Ann Arbor, in 1898.

MISSOURI

Society News.—The St. Louis Medical Society was addressed, April 22, by Drs. John H. Hershey on "Lateral Approach to a Diverticulum of the Cervical Portion of the Esophagus" and Forest H. Staley, "Some Physicochemical Studies on a Case of Pancreatic Fistula Following Operation for Acute Hemorrhagic Pancreatitis." Dr. John H. Peck, Oakdale, Iowa, discussed "An Evaluation of the Modern Medicines Used in the Diagnosis and Treatment of Pulmonary Tuberculosis" before the society, April 8.—Dr. James H. Dangle, Kansas City, presented "Arterial Hypertension—A Critical Review of Recent Progress in Classification, Etiology and Treatment" before the Jackson County Medical Society in Kansas City, April 22, and Dr. Frederick A. Jostes, St. Louis, showed a motion picture on "Backache."

Gibbs Medal to Dr. Doisy.—Edward A. Doisy, Ph.D., professor of biochemistry and director of the department, St. Louis University School of Medicine, St. Louis, received the 1941 Willard Gibbs Medal of the Chicago section of the American Chemical Society at a meeting in Chicago, May 23, in recognition of "conspicuous contributions to chemistry." The presentation was made by William Lloyd Evans, Ph.D., professor and chairman of the department of chemistry, Ohio State University, Columbus, president of the American Chemical Society, and Ernest H. Volwiler, Ph.D., of the Abbott Laboratories, North Chicago, Ill., described the scientific achievements of Dr. Doisy, who is credited with first isolating pure vitamin K. Born in Hume, Ill., in 1893, Dr. Doisy took his doctorate at Harvard University, Cambridge, Mass., in 1920. He was assistant in biochemistry at Harvard Medical School, Boston, from 1915 to 1917. He was instructor, associate and associate professor of biochemistry at Washington University School of Medicine, St. Louis, from 1919 to 1923, when he went to St. Louis University. He received the gold medal of the St. Louis Medical Society in 1935, the Philip A. Conné Medal of the Chemists Club of New York in 1935 and the St. Louis Award in 1939. He has given special lectures throughout the country from time to time and has written numerous articles on his researches.

NEW JERSEY

Society News.—Dr. Evan W. Thomas, New York, addressed the Bergen County Medical Society, Englewood, May 13, on "Modern Treatment of Syphilis."—At a meeting of the Morris County Medical Society at the Shongum Mountain Sanatorium, Morristown, May 15, the speakers were Drs. Samuel C. Haven, Morristown, and William K. Booth, Boonton, on early history and recent activities, respectively, of the sanatorium and Dr. Paul Geary, Plainfield, on "Surgical Treatment of Pulmonary Tuberculosis."—Speakers at the annual meeting of the Cape May County Medical Society, Ocean City, May 13, included Drs. Chester I. Ulmer, Gibbs-town, on "Are You Aiding the Public in Self Medication?" and Frederic J. Quigley, Union City, "Why a Legislative Committee?"

NEW YORK

Mental Hygiene Unit in County Health Department.—Dr. George M. Lott of Amityville, L. I., has been appointed director of a new mental hygiene unit in the Suffolk County Department of Health, with headquarters in Riverhead. The county board of supervisors authorized an appropriation last October of \$17,000 to establish the service, and state aid will also be available, it was said. This is believed to be the first mental hygiene service organized under a county health department. It was supported by the medical profession and by many state and local health and civic agencies. In addition to Dr. Lott, the personnel will consist of a psychologist, two psychiatric social workers and a clerk. Dr. Lott graduated from the University of Colorado School of Medicine in 1928. He has served a fellowship in psychiatry at the Institute for Child Guidance in New York and for four years was director of the bureau of child guidance and state psychiatrist of Rhode Island. From 1936 to 1939 he was psychiatrist in the bureau of child guidance of the board of education of New York City and has recently been engaged in private practice.

New York City

Doctors' Concert.—The Doctors' Orchestra Society of New York held its third annual concert at Town Hall, May 9, under the auspices of the Physicians' Wives League of Greater New York for the aid of their relief fund. Fritz Mahler conducted and Michel Piastro, concertmaster of the New York Philharmonic Symphony Orchestra, was the soloist.

Hospital News.—Dr. Abraham M. Rabiner, Brooklyn, has been appointed clinical director of the Jewish Sanitarium and Hospital for Chronic Diseases in conjunction with a program to further research in the field of incurable diseases.—Dr. John P. Peters, New Haven, Conn., addressed the Journal Club of Montefiore Hospital, March 17, on "Clinical Implications of the Newer Knowledge of Carbohydrate Metabolism." Dr. Maurice B. Visscher, Minneapolis, was the speaker, April 14, on "Experimental Analyses of the Action of Several Car-

diac Glucosides," and Dr. Samuel Soskin, Chicago, spoke, May 7, on "Newer Concepts of Diabetes."—Dr. John H. Travis, superintendent of Willard State Hospital, Willard, N. Y., has been appointed superintendent of Manhattan State Hospital on Ward's Island. Dr. John R. Knapp has recently been acting superintendent at Manhattan.—Roosevelt Hospital has organized a catastrophe unit to serve at major accidents. Two teams of thirteen physicians each and three teams of thirteen nurses each were to be selected for service, available at all hours. Establishment of the unit was financed by a trustee of the hospital.

NORTH CAROLINA

State Tuberculosis Meeting.—The annual meeting of the North Carolina Tuberculosis Association was held in Greensboro, April 30, with Dr. Harry E. Kleinschmidt, director of health education of the National Tuberculosis Association, New York, as the guest speaker. Dr. Charles W. Armstrong, Salisbury, was elected president.

Personal.—Dr. Dudley W. Smith, Waynesville, has gone to England to serve with the American Hospital near London for six months, it is reported.—Dr. Will H. Lassiter Jr., Selma, has been appointed health officer of Johnston County to succeed Dr. James H. Bunn Jr., Smithfield, who resigned to enter military service.—Dr. Paul R. Macfadyen Jr., Concord, recently acting health officer of Cabarrus County, has been appointed in Richmond County to succeed Dr. Tidal Boyce Henry, Rockingham.

Special Societies.—Dr. Archibald A. Barron, Charlotte, was elected president of the North Carolina Neuropsychiatric Association at a meeting in Durham recently; Dr. Fonso B. Watkins, Morganton, vice president, and Dr. Robert Burke Suitt, Durham, secretary. Dr. Walter Freeman, Washington, D. C., was the guest speaker on "Indications, Procedures and Results in Prefrontal Lobotomies."—Dr. Brodie C. Nalle, Charlotte, was elected president of the North Carolina Obstetrical Society at a meeting at Mid-Pines in March.—Dr. James B. Whittington, Winston-Salem, was named president-elect of the North Carolina Hospital Association at a business meeting in Charlotte, April 23, and Mr. J. Lyman Melvin, Rocky Mount, became president.

PENNSYLVANIA

Hospital Addition.—A new wing providing additional facilities especially for the diagnostic department was recently dedicated at George F. Geisinger Memorial Hospital, Danville. The third floor has operating rooms, offices and space for the urologic department; the second is given over entirely to the department of medicine with examining rooms and clinical laboratories among other facilities; the basement floor provides a central supply room, sterilizing room and solution preparation room. The architects were Stevens and Lee, Boston.

Philadelphia

Jarecki Lecture.—The seventh annual Edwin A. Jarecki Memorial Lecture was presented at the Jewish Hospital, May 1, by Dr. Frank H. Lahey, Boston, President-Elect of the American Medical Association. His subject was "Lesions of the Stomach, Duodenum and Jejunum."

Strittmatter Award to Dr. Reeves—Da Costa Oration.—The Philadelphia County Medical Society conferred the Dr. I. P. Strittmatter Award, a gold medal and scroll, on Dr. Rufus S. Reeves at a meeting, May 2. The award was given to Dr. Reeves in recognition of his work as chairman of the annual Postgraduate Institute sponsored during the past six years by the county society. Dr. Reeves was president of the county society in 1939 and is now chairman of its committee on nutrition and deficiency diseases. He graduated from the University of Pennsylvania School of Medicine in 1912. On the same evening Dr. George P. Müller, professor of surgery, Jefferson Medical College, delivered the annual Dr. John Chalmers Da Costa Oration on "Surgical Aspects of Cancer of the Stomach."

UTAH

State Medical Meeting in Salt Lake City.—The forty-seventh annual meeting of the Utah State Medical Association will be held at Kingsbury Hall, University of Utah, Salt Lake City, June 12-14, under the presidency of Dr. Alfred C. Calister, Salt Lake City. Guest speakers will include:

Dr. James Barrett Brown, St. Louis, Management of Compound Facial Injuries; Surgical Lesions of the Face, Mouth and Neck.
Dr. Alfred J. Cone, St. Louis, Ear, Nose and Throat Problems in Rheumatic, Diabetic and Nephritic Children.

Dr. Robert J. Crossen, St. Louis, Diagnosis, Prophylaxis and Treatment of Uterine Carcinoma; Functional Uterine Bleeding; Dysmenorrhea.

Dr. Everett D. Plass, Iowa City, Hyperemesis Gravidarum; Treatment of Puerperal Infections.

Dr. John M. Rector, San Francisco, Present Status of Immunization Procedures; the Acutely Ill Child.

Dr. Edward H. Rynearson, Rochester, Minn., Hyperinsulinism; Endocrinology—A Critical Review.

Dr. Cyrus C. Sturgis, Ann Arbor, Mich., Treatment of the Anemias; The Hemorrhagic Diseases.

The guest speakers will also conduct clinics. "The Doctor's Place in National Defense" will be the theme of a symposium and round table discussion Thursday evening. A similar program will be held on industrial diseases Saturday afternoon with the following speakers: Donald E. Cummings, B.S., associate professor of medicine, University of Colorado School of Medicine, Denver, on "Chemical Hazards in Industry"; Mr. Homer L. Sampson, New York, "X-Ray Considerations in Chest Diagnosis," and Dr. Carl M. Peterson, Secretary, Council on Industrial Health, American Medical Association, Chicago, "Industrial Hygiene in National Defense." At the annual banquet Friday evening Dr. Russell G. Frazier, Brigham Canyon, medical officer for the U. S. Antarctic Expedition, will discuss his experiences in the Antarctic.

VIRGINIA

Postgraduate Course in Medicine.—The University of Virginia Department of Medicine, University, is offering a course on recent advances in medicine, June 16-21. The registration limit is fifty. The first similar course was given last year. This year there will be clinics instead of ward rounds, according to the announcement. Final reservations must be made by June 10. Dr. Staige D. Blackford, Box 1174, University Post Office, Charlottesville, is chairman of the committee on postgraduate clinics.

The McGuire Lectures.—Dr. Alfred Blalock, professor of surgery, Vanderbilt University School of Medicine, Nashville, Tenn., delivered the McGuire Lectures at the Medical College of Virginia, Richmond, April 24-25. His subjects were "Pathogenesis of Shock" and "Prevention and Treatment of Shock." The annual postgraduate lectures were presented at the college, April 25, on the general topic of treatment of trauma and shock in wartime. Speakers on this program were:

Dr. Lennox R. Broster, London, England, Recent Developments in the Treatment of War Wounds.

Lieut. Col. David N. W. Grant, medical division, U. S. Army Air Corps, Occupational Fatigue as Manifested in Flying Personnel.

Dr. Henry K. U. Beecher, Boston, Clinical Aspects of Anesthesia and Shock.

Dr. Claude C. Coleman, Richmond, Penetrating Wounds of the Brain.

Dr. Harry J. Warthen Jr., Richmond, Gas Bacillus Infection.

WISCONSIN

Dr. Buerki Goes to University of Pennsylvania.—Dr. Robin C. Buerki, medical superintendent of the State of Wisconsin General Hospital, Madison, has been appointed dean of the University of Pennsylvania Graduate School of Medicine to succeed George H. Meeker, Ph.D., who will retire October 1. In addition Dr. Buerki will be director of hospitals of the University of Pennsylvania, a newly created post in which he will have direction over the University Hospital, the Graduate Hospital and the Orthopedic Hospital, the university announces. Dr. Buerki, who graduated from the University of Pennsylvania School of Medicine in 1917, is also executive secretary to the dean of the University of Wisconsin Medical School and professor of hospital administration in the school. From 1938 to 1940 he was on leave from Wisconsin to direct a survey of graduate medical education for the Commission on Graduate Medical Education. Dr. Buerki has been president of the American Hospital Association and of the American College of Hospital Administrators. Dr. Meeker has been dean of the graduate school of medicine at Pennsylvania since it was opened in 1919 and has also served as manager of the Graduate Hospital, professor of chemistry in the school of medicine and professor of biochemistry in the graduate school. He received the degree of doctor of philosophy from Lafayette College, Easton, Pa., in 1893 and has received honorary doctorates in science from the University of Pennsylvania and Villanova College and in laws from Ursinus and Lafayette colleges.

GENERAL

New Director of Scientific Research at Meat Institute.—Henry R. Kraybill, Ph.D., professor and head of the department of agricultural chemistry, Purdue University, Lafayette, Ind., has been appointed director of the department of scientific research of the American Meat Institute, succeeding Winford Lee Lewis, Ph.D., who asked to be relieved because of ill health. Dr. Lewis, who has held the position since 1924, will be associated with the institute in an advisory capacity. Dr. Kraybill has been professor and head of the department at Purdue since 1926 and concurrently state chemist and seed commissioner.

Meeting of Thoracic Surgeons.—The American Association for Thoracic Surgery will hold its annual session in Toronto, Canada, June 9-11, under the presidency of Dr. Fraser B. Gurd, Montreal, whose official address will be on "Pulmonary Abscess." The program will consider the following topics, among others: surgical treatment of pulmonary tuberculosis with and without endobronchial involvement, carcinoma of the lung, carcinoma of the esophagus and pulmonary suppuration. The entire first day and evening will be devoted to the tuberculosis problem. At the annual dinner Tuesday evening Wing Commander George E. Hall, Weston, Ont., will speak on "Aviation Medicine."

Private Flying Safety Record Improves.—Airlines in private use flew 991,842 miles per fatal accident, 1,168,367 per pilot fatality and 1,659,420 per passenger fatality in 1940, the Civil Aeronautics Administration reported. In 1936 they flew only 586,920 miles per fatal accident. In 1940 there were 231 fatal accidents in which 196 pilots, 138 passengers, 13 students and 9 ground crew or third parties, a total of 356, were killed. In the last six months of 1940 there were 30,000 students in training in the Civilian Pilot Training Program. They flew 96,000,000 miles during the year with a total of 31 fatalities, including both students and instructors, the report stated. This shows 3,160,000 miles flown per fatality, the highest figure ever established in private flying, it was said.

Changes in Status of Licensure.—The Illinois State Department of Registration and Education announces the following:

Dr. Charles E. Leary, Du Bois, license restored Oct. 9, 1940.
The Massachusetts Board of Registration in Medicine recently reported the following:

Dr. Michael Litvich, Revere, license restored, March 13.
Dr. Anthony P. Carogana, Chelsea, license restored.
The New York State Board of Medical Examiners recently reported the following action:

Dr. Alice M. Heinrich, Chairman, New York, license revoked.
Dr. Isaac Workman, Brooklyn, license revoked, February 21.
The Virginia State Board of Medical Examiners recently reported the following action taken Dec. 4, 1940:

Dr. Robert S. Fitzgerald, Logan, W. Va., Virginia license restored.
Dr. Ulysses S. McCoy, Petersburg, license restored.
The Public Health Council of West Virginia recently reported the following action:

Dr. Elmer Groves Kessler, formerly of Williamsburg, license revoked Oct. 31, 1940, following conviction of a felony.
Dr. John B. Rosier, Philippi, license restored, March 3.
American Neurological Association.—The sixty-seventh annual meeting of the American Neurological Association will be held at the Ambassador Hotel, Atlantic City, June 9-11.

Speakers will include:
Drs. Eldridge H. Campbell Jr., Nathan F. Fradkin, Basile Lipetz, Albany, N. Y., Myasthenia Gravis Treated by Removal of Thymic Tumor: Report of Two Cases.
Drs. James C. White and Jost J. Michelsen, Boston, Treatment of Obstructive Hydrocephalus in Adults by Drainage of the Ventricular System.
Drs. Andrew J. E. Akelaitis, Wilford A. Risteen and William P. Van Wagenen, Rochester, N. Y., and R. Yorke Herren, Portland, Ore., A Contribution to the Study of Dyspraxia and Apraxia Following Partial and Complete Section of the Corpus Callosum.
Drs. Herman I. Wortis, Norman H. Joffe, Martin H. Stein and Ernest Heuding, New York, Clinical and Chemical Studies in Wernicke's Syndrome.
Drs. Howard A. Howe and David Bodian, Baltimore, Relation of Fiber Pathways to Local Immunity in Experimental Poliomyelitis.
Drs. James Lawrence Pool and Paul F. A. Hoefler, New York, Contribution of Cortical Impulses in Experimental Convulsive Seizures.
Joseph L. Miller Jr., Baltimore, Degeneration of the Primary Sensory Neuron in Pigs from Nutritional Deficiency.
Dr. William Horsley Gantt and W. J. Brogden, Ph.D., Cerebellar Conditioned Reflexes.

The American Association of Neuropathologists will hold its meeting at the Ambassador Hotel on June 9.

Bequests and Donations.—The following bequests and donations have recently been announced:

New York Dispensary, Presbyterian Hospital, New York Eye and Ear Infirmary, Lincoln Hospital and Home, New York Hospital and New York Orthopaedic Dispensary and Hospital, each \$100,000 by the will of Miss Caroline White. All are in New York.
Mount Sinai Hospital, New York, \$1,000 by the will of the late Mrs. Henrietta Hirschman; \$35,000 under the will of the late William N. Cohen.
New York Post-Graduate Medical School and Hospital, \$25,000 from the will of the late Mrs. Florence Brevoort Eickemeyer, Yonkers, N. Y.
Abington Memorial Hospital, Abington, Pa., and the Philadelphia Health Council, \$1,000 each by the will of the late Mrs. George Horace Lorimer.
Es'Dora Hospital, Walterboro, S. C., \$1,000 from the estate of Frank L. Hutton, New York.
New York Orthopaedic Dispensary and Hospital, \$100,000 and a contingent bequest of the residuary estate of Miss Josephine C. Smith, Philadelphia.
Montefiore, Mount Sinai and Beth Israel hospitals, New York, \$106,863 each by the will of the late James Ulmann.
Lake County Memorial Hospital, Painesville, Ohio, \$5,000 by the will of Mrs. Alice Maury Parmelee.
Deaconess Hospital, Spokane, Wash., property valued at \$233,362.50 from the estate of the late Dr. Theodore Chamberlin, Concord, Mass., in memory of his brother, Frederick Dean Chamberlin, a Spokane pioneer.

Vital Statistics for 1939.—The death rate for the United States registration area in 1939 was 10.6, the lowest ever recorded, according to a final report issued by the U. S. Bureau of the Census. The birth rate declined from 17.6 per thousand of estimated population in 1938 to 17.3 in 1939. There were 2,265,588 births and 1,387,897 deaths reported for the year. Death rates for such causes as heart disease, cancer and diabetes were higher than ever, but those for influenza and pneumonia, for tuberculosis and the infant and maternal mortality rates were the lowest ever reported for the death registration area. Death rates for selected causes showed 43.2 per hundred thousand of population for tuberculosis, 59.4 for pneumonia and 16.4 for influenza. Cancer showed the highest rate for cancer of the digestive organs and peritoneum, 54.9; female genital organs 15.9, breast 11.4 and other forms 35.6. The rate for rheumatic diseases of the heart 20.1, diseases of coronary arteries and angina pectoris 68.5, other forms of heart disease 14.2, which was smaller than that for the preceding four years shown in the table. Motor vehicle accidents gave a rate of 24.8 and other accidents 46.1. A table analyzing causes of death in infants under 1 year of age gave the highest causes as premature birth, 32,251 out of a total of 108,846 infant deaths; pneumonia 13,786; congenital malformations 10,390; injury at birth 10,164; diarrhea, enteritis etc. 9,096; influenza transportation accidents, 30,468 occurred in automobile accidents; 1,329 in train and automobile accidents and 3,394 in other railway accidents; 1,087 in water transport and 396 in air transport.

CANADA

Balfour Lectureship.—Dr. David Cheever, associate professor of surgery emeritus, Harvard Medical School, Boston, was the speaker for the fifteenth annual Donald C. Balfour Lectureship in Surgery, April 5, at the University of Toronto Faculty of Medicine. His subject was "War—Its Tolls and Its Tributes."

Canadian Medical Association.—The seventy-second annual meeting of the Canadian Medical Association will be held at the Hotel Alexandra, Winnipeg, June 23-27, under the presidency of Dr. Duncan Graham, Toronto. Among speakers at general sessions will be:

Dr. William F. Braasch, Rochester, Minn., The Surgical Kidney as a Factor with Hypertension.
Dr. Rustin McIntosh, New York, Jaundice.
Drs. Ralph M. Tovell and Curtiss B. Hickcox, Hartford, Conn., The Present Status of Cyclopropane.
Dr. Adam F. Menzies, Morden, Man., Postwar Medical Problems.
Dr. Gordon E. Richards, Toronto, Ten Years' Progress in the Radiotherapy of Oral Cancer.

The section of military medicine will have a symposium on "Medical Aspects of Casualties Returning from Overseas," with the following speakers: Lieut.-Col. Andrew M. Davidson, Capt. Harry S. Atkinson, Lieut.-Col. Thomas E. Holland, Major Harry G. Grieve and Major Morley R. Elliott, all of the Royal Canadian Army Medical Corps; Wing Commander George E. Adamson and John A. Gunn, Winnipeg. A message from the association states that physicians of the United States will be welcome to this meeting, that no passports are required and that there are no financial or commercial restrictions. Other hotels in addition to the Alexandra are the Fort Garry, St. Charles, Marlborough, St. Regis and the Mall. There are hard surface, all weather roads leading to Winnipeg via Emerson or Kenora.

The Ophthalmic Quacks of London

An ophthalmic surgeon, Mr. E. W. Brewerton, has contributed to *St. Bartholomew's Hospital Journal* an account of the ophthalmic quacks who have flourished in London during the last twenty years. These quacks may be classified as (1) those who say that every chronic eye condition can be cured by glasses, (2) those who claim the same for other means, usually electricity, (3) those who claim to relieve every error of refraction by exercises and say that all glasses are unnecessary, (4) the osteopaths, who will guarantee a cure for everything from pruritus ani to detached retina by replacing a displaced vertebra and (5) the psychoanalysts. The first class orders patients suffering from errors of refraction, cataract, optic atrophy or macular degeneration to read for a certain number of hours daily with strong magnifying glasses. A man named Fournier, who was backed by a well known admiral, was the originator of this method. He claimed that his glasses were of secret manufacture. He flourished for many years until the business was taken over by Wright, who died after a few years lucrative practice, to be followed by his brother. The present proprietor of the business displays in his waiting room a printed notice that he cured a certain cabinet minister when London ophthalmologists failed.

The quacks who claim to cure by electricity flourish on the many who have a horror of operation on the eye. A man with advancing cataract was told to attend three times a week at a fee of \$30. One pole of a galvanic battery was applied to the neck and the other was passed round the orbit. At every visit the nurse told him he was better, but as his vision deteriorated the chair was put nearer to the type to make him believe that he was improving. At least six rooms used in the house were always full; the proprietor must have been making \$250,000 a year. The patient was told that his was a very difficult case and that another course was necessary. This he declined.

Those who treat presbyopia and errors of refraction by exercise and say that all glasses are unnecessary deny that accommodation depends on the ciliary muscle and attribute it to the extrinsic muscles of the globe. Their leader says that the more the eyes are used the stronger they get and that light, especially sunlight, is a cure for all kinds of defective sight. Mr. Brewerton mentions the case of a boy with 4 diopters of myopia who was promised a cure. After twelve months' treatment by exercises he could not see 6/60 and his error is now 4.5 diopters.

Marriage of Relatives

Since 1603 the Church of England has had "A Table of Kindred and Affinity, wherein whosoever are related are forbidden in Scripture and our Laws to marry together." This table was drawn up by Calvin but is ultimately derived from the Levitical code. It became the law of England in 1603 and remained so without modification for three hundred years. There are thirty prohibitions for each sex. Close relation by marriage was as much a ground of prohibition as consanguinity. Thus marriage with a deceased wife's sister was banned equally with marriage with a sister. Reform which began in 1907, made marriage with a deceased wife's sister legal. The whole subject was reconsidered recently when the archbishop of Canterbury appointed an ecclesiastical commission which has presented a report. Expert evidence was obtained on the scientific aspect.

Prof. J. B. S. Haldane, F.R.S., the geneticist, points out that the danger in consanguineous marriages is the production in the

offspring of diseases depending on recessive genes. Examples are furnished by albinism, porphyria, xeroderma pigmentosum, keratoma malignum, ichthyosis congenita, retinitis pigmentosa, amaurotic idiocy, deaf-mutism and congenital diplegia. In consanguineous marriages the probability of a recessive gene for these conditions being present in both parents is much greater than when the parents are not related. Thus albinism occurs with a frequency of one in forty thousand when the parents are not related, but one in eight hundred in incestuous brother and sister unions and in one in three thousand two hundred in first cousin unions. But Haldane says that an absolute line of prohibition cannot be drawn on biologic grounds. Two goods—freedom and health—must be balanced against each other. He would not recommend prohibition of the marriage of first cousins but does not regard its prohibition as unscientific. He recommends that all existing prohibitions based on consanguinity, such as uncle and niece, should be continued. But there is no valid scientific grounds for prohibiting such marriages as that of a man with his deceased wife's daughter, though the idea excites slight repugnance in him.

The principal recommendation of the commission is a revised "table" differing from the original one in omitting the prohibitions of marriage with sister-in-law, sister's son's wife and wife's niece. But some of these have already been abolished by Parliament. It will be seen that none of these marriages are consanguineous, so that all the original prohibitions of this nature stand.

AUSTRALIA

(From Our Regular Correspondent)

Feb. 17, 1941.

Causes of Invalidism in Military Service

A clinical survey of the first group of invalid soldiers to be returned to Australia from abroad confirms the instructions already issued by the director general of medical services regarding the standards of physical fitness for recruits. All the patients carried on this voyage, and they include men from the New Zealand contingent as well as members of the Australian Imperial Force, have been boarded out as unfit for further service in the army abroad. Of 208 cases studied, 61 were due to diseases of or injury to the nervous system. Cases listed under the board heading "anxiety states" are subdivided into three groups: (1) anxiety states developed after enlistment without any previous history of "nerves" or "nervous breakdown," (2) anxiety states associated with a previous history of mental breakdown and (3) anxiety states with visceral fixation: (a) functional dyspepsia, (b) cardiac neurosis. Of all these cases twice as many occurred in the second as in any other group. Careful inquiry into the past histories of these patients showed that they were capable of "carrying on" in civil life in spite of minor breakdowns; but the strain of military life in active service quickly revealed their mental instability. A large number might have been excluded from the army if a truthful history had been given in the first place; failing this, however, there is no certain method whereby these potential invalids can be detected. Epilepsy, postconcussional headache and mental aberration accounted for the remainder of nervous disabilities. The postconcussional headache syndrome deserves consideration, for patients in this group could not stand any training at all. All had definite histories of severe head injuries, with periods of unconsciousness at the time of the accident, and in many instances scalp scars could be seen or irregularities felt in the bones of the skull. From a study of these and previous similar cases it is advised that no recruit with a history of severe concussion or head injury should be accepted for active service.

Diseases of the respiratory system (58) have been divided into nontuberculous (mostly asthma) and tuberculous. In view

of the 41 cases of asthmatic disability, it has been recommended that any soldier who has suffered from asthma, or a long-standing cough or in whom rhonchi can be detected in the lungs in the absence of a definitely acute infection, should be excluded. Of the 17 patients with pulmonary tuberculosis, 11 were recalled on account of lesions discovered in the roentgenograms prior to embarkation. In the other 6 cases there was no record in the available papers of the result of routine roentgen examinations, but in all cases the diagnostic films suggested a chronic lesion of more than a few months duration. This provides further proof of the usefulness of routine radiologic examination of the lungs on enlistment.

The high proportion of patients (42) suffering from peptic ulcer demands consideration. In 88 per cent of these invalids symptoms of dyspepsia had been present prior to enlistment, and 9 had undergone operations for ulcers. Only 5 patients were convinced that the symptoms had originated during active service. This suggests that active service conditions are more potent in precipitating a relapse than in producing the disease *de novo* and confirms the accepted view that patients with peptic ulcers should exercise lifelong care with regard to their diet and living conditions.

In view of these findings it has been recommended emphatically in Australia that subjects of nervous dyspepsia, hyperchlorhydria or severe gastric disturbances should not go abroad.

The incidence of painful back as a cause of invalidism is surprisingly high and suggests that a careful inquiry into the past history of back strain should be made prior to enlistment, particularly in men over 35 years of age.

The special attention paid to examination of the feet of recruits has avoided any large wastage because of foot disabilities, and only 8 were invalidated home on this account.

It is gratifying to note, and reflects praise on the army medical authorities, that the incidence of tropical diseases and of venereal infection are almost negligible.

A review of these 208 cases then reveals a low incidence of diseases with detectable physical signs. The larger groups consist of those conditions which cause symptoms rather than physical signs. The inference is that, although the physical examination of recruits has been of a high standard, sufficient emphasis has not been laid on a careful clinical history.

Conference on Public Health

At a conference convened by the director general of health in New Zealand, Dr. M. H. Watt, to consider public health problems with especial reference to war conditions, attention was drawn to the high proportion of recruits who on medical examination were rejected for foot trouble. A preliminary investigation into the suitability of the lasts used for making footwear in New Zealand, prompted by this observation, pointed to the fact that many of the lasts were unsatisfactory; and it has been decided to bring the matter to the notice of the Department of Industries and Commerce through the Royal Australian College of Surgeons. At the same conference it was pointed out that influenza, rubella and cerebrospinal meningitis were at the moment of only secondary importance and presented no special difficulties. Attention was drawn, however, to the absence of any reference to sinus infections in the medical examinations of recruits.

The question of mass radiography in tuberculosis control was discussed at length. The success of the routine chest roentgen examination of recruits had brought the matter into prominence in New Zealand, and steps had already been taken in Wellington to investigate the application of miniature radiography to the local civilian problem.

With regard to methods of quarantine and port health inspection, the conference resolved that full quarantine (by which is meant the detention in quarantine stations of passengers and companies of ships on which a case of quarantinable disease has occurred) is highly expensive, inefficient and

impracticable and should be abandoned in favor of the English system whereby infectious patients on arriving ships are sent to isolation hospitals while other persons on board are allowed to go about their business under the surveillance of the local medical officers of health.

It was reported that the incidence of gonorrhea and syphilis in military camps since the outbreak of war had been particularly small and that the introduction of facilities for preventive treatment had met with considerable success.

Dr. Muriel Bell, nutrition expert in the department of health, summarized the existing errors of diet in New Zealand. The average person probably (a) ate too much meat, sugar, cakes and confectionery and (b) ate too little fish, raw fruit, raw vegetables, milk, eggs, unrefined cereals and cheese. It was likely that in most homes there was a suboptimal intake of vitamin B₁ and that, as the majority of people were impervious to propaganda about whole meal bread, it was necessary to take steps to improve the vitamin content of white bread. This could be done either by adding synthetic vitamin B₁ to the bread or by increasing and improving the yeast used.

Hydatid Disease in New Zealand

A study of the recent data accumulated by Sir Louis Barnett, chairman of the New Zealand Hydatid Research Committee, on the incidence of hydatid disease in New Zealand reveals that about 120 new cases of the disease are treated in that country each year and that about 16 of them are fatal. About half the country's sheep and cattle have livers and lungs infected with hydatids, while a third or more of all country dogs harbor the adult parasite *Taenia echinococcus*. In spite of an intensive campaign of prevention there is no definite evidence yet that, taking New Zealand as a whole, hydatid infection is on the wane. The South Island, though only half as populous as the North Island, yet has almost as many cases of hydatid disease. This disproportion is largely due to a particularly heavy infection in the Canterbury district.

Marriages

CHARLES GRANGER CHAPMAN, Columbia, S. C., to Miss Florence Radcliffe Clauss of Charleston, March 1.

ALFRED FRANKLIN HAMMOND JR., Pollockville, N. C., to Miss Lucy Olivia Barrow of Grifton in March.

PHILLIP WEBSTER HORN, Ardmore, Okla., to Miss Ruth Elizabeth Johnson of New Orleans, March 17.

COURTLANDT DIXON BERRY, Rahway, N. J., to Miss Frances Woodward of Winter Park, Fla., February 15.

RALPH CARBONE, Fort Lee, N. J., to Miss Ruth Stearn of Grantwood, at Camp Livingston, La., recently.

JAMES BARRETT CUMMINS, Gloversville, N. Y., to Dr. Ella E. Foster of Glenside, Pa., March 15.

ROBERT LEON BOURLAND, Memphis, Tenn., to Miss Rosa Elizabeth Landess of Murray, Ky., March 5.

LEON TOLAND KENNEDY, Winston-Salem, N. C., to Miss Irene Storm in Mooresville, March 19.

ALEXANDER A. YORK, High Point, N. C., to Mrs. Mary E. Inman of Washington, D. C., March 2.

MARCUS WHITMAN HEDGCOCK, Champaign, Ill., to Miss Erma Bissell of Chicago, February 19.

GEORGE L. CARRINGTON, Burlington, N. C., to Miss Elizabeth Scott of Philadelphia, March 1.

WILLIAM J. LANCASTER, Wilmington, N. C., to Miss Jean Lunden of Tampa, Fla., in March.

ERASTUS GENAIR GOODMAN, Leland, N. C., to Miss Elizabeth Zuidema of Hampton, Va., in March.

WILLIAM L. KIRKPATRICK to Miss Ellie Thompson, both of Waynesville, N. C., recently.

CONNELL HUTCHISON MILLER to Miss Nettie Stewart, both of Sligo, Pa., March 14.

ROBERT L. WADE to Miss Mabel Mains, both of Coldwater, Mich., in April.

Deaths

Allen Kramer Krause, Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1907; assistant in pathology, 1907-1908, instructor in pathology, 1908-1909, associate professor of medicine and director of the Kenneth Dows Tuberculosis Research Laboratory from 1916 to 1929, visiting lecturer in medicine from 1930 to 1932 and lecturer in medicine in 1932 at his alma mater; fellow by courtesy in epidemiology, Johns Hopkins University School of Hygiene, from 1936 to 1939; in charge of the tuberculosis division of the Johns Hopkins Dispensary and associate physician, Johns Hopkins Hospital, from 1919 to 1929; director of the Desert Sanatorium, Tucson, Ariz., from 1929 to 1937; clinical professor of medicine, Stanford University School of Medicine, San Francisco, from 1929 to 1937; clinical professor of medicine at the University of Southern California School of Medicine, Los Angeles, from 1932 to 1937; member of the Association of American Physicians, American Society for Clinical Investigation, American Clinical and Climatological Association, American Association of Anatomists, American Association of Pathologists and Bacteriologists and the Society of American Bacteriologists; fellow of the American College of Physicians; for many years member of the medical council of the Veterans Administration; assistant and assistant director of the Saranac Laboratory for Study of Tuberculosis from 1906 to 1916; in 1931 was awarded the Trudeau Medal of the National Tuberculosis Association; author of "Environment and Resistance in Tuberculosis" and "The Evolution of Tubercle"; contributor to Nelson's Loose Leaf System of Medicine, Osler's Modern Medicine, Cecil's Textbook of Medicine, Piersol's Cyclopedia of Medicine and the Encyclopedia Britannica; formerly managing editor and editor of the *American Review of Tuberculosis*; for many years editor of the American section of *Tubercle*; aged 60; died, May 12.

Matthias Nicoll Jr., Rye, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1892; chairman of the Section on Preventive and Industrial Medicine and Public Health of the American Medical Association, 1925-1926; formerly clinical professor of infectious diseases, University and Bellevue Hospital Medical College, New York; chief of the division of diagnosis and assistant director of the New York City Department of Health from 1908 to 1914; secretary and director of public health education, New York State Department of Health from 1915 to 1917; deputy commissioner of health from 1917 to 1923; commissioner of health of New York from 1923 to 1930; commissioner of health of Westchester County from 1930 to 1938; past president of the State and Provincial Health Authorities of North America; member of the governing council and executive board of the New York Academy of Medicine; for many years attending physician to the Willard Parker Hospital, Seton Hospital and the New York Foundling Hospital, New York; aged 73; died, May 13.

Henry Keller Mohler, Philadelphia; Jefferson Medical College of Philadelphia, 1912; in charge of the laboratory of clinical medicine, 1913-1914, instructor in medicine from 1913 to 1922, demonstrator of medicine from 1922 to 1925, associate in medicine from 1925 to 1929, assistant professor from 1929 to 1932, associate professor from 1932 to 1938, clinical professor of therapeutics from 1936 to 1938 and since 1938 dean and Sutherland M. Prevost professor of therapeutics at his alma mater; medical director of the Jefferson Medical College Hospital from 1914 to 1938, assistant physician from 1932 to 1938, attending physician since 1938 and physician in charge of the department of electrocardiology; served during the World War; fellow of the American College of Physicians; charter fellow of the American College of Hospital Administrators; past president of the Hospital Association of Pennsylvania and of the Philadelphia Heart Association; director of the Philadelphia Health Council and Tuberculosis Association; member of the board of directors of the Children's Heart Hospital; member of the city board of health; aged 54; died, May 16, of cerebral hemorrhage.

Dudley Almonte Smith, San Francisco; Jefferson Medical College of Philadelphia, 1900; member of the House of Delegates from 1927 to 1930 and in 1932 and chairman of the Section on Gastro-Enterology and Proctology of the American Medical Association, 1930-1931; past president of the American Proctologic Society; fellow of the American College of Surgeons; clinical instructor in surgery at the University of California Medical School; aged 70; on the staffs of the Uni-

versity of California Hospital, St. Luke's Hospital, Southern Pacific General Hospital and Mary's Help Hospital, San Francisco; Alta Bates Hospital, Berkeley; Providence Hospital and Peralta Hospital, Oakland, where he died, April 24.

Forrest Mullins Barfield, Atlanta, Ga.; Atlanta Medical College, 1915; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; served during the World War; instructor in surgery at the Emory University School of Medicine, from 1919 to 1930; associate visiting surgeon, Emory University Hospital; associate visiting gynecologist and obstetrician, Georgia Baptist Hospital; associate surgeon, Crawford W. Long Memorial and Piedmont hospitals; aged 49; died, April 17, of heart disease.

Paul Dee Berrisford, St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1912; member of the Minnesota State Medical Association and of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; clinical assistant professor of ophthalmology at his alma mater, now the University of Minnesota Medical School; on the staffs of the Children's, St. Luke's and Charles T. Miller hospitals; aged 55; died, April 17, of cerebral hemorrhage.

John Charles McCoy, Paterson, N. J.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1892; fellow of the American College of Surgeons; served during the World War; consulting surgeon, Paterson General Hospital, Dover (N. J.) General Hospital, Holy Name Hospital, Teaneck and the Good Samaritan Hospital, Suffern, N. Y.; aged 74; died, April 17, in the Harkness Pavilion, Columbia Presbyterian Medical Center, New York, of intestinal obstruction.

Charles Herbert Holt, Pawtucket, R. I.; Harvard Medical School, Boston, 1906; past president and vice president of the Rhode Island Medical Society; member of the New England Surgical Society; fellow of the American College of Surgeons; served during the World War; formerly mayor of Pawtucket; at one time city health officer; served on the staff of the Memorial Hospital in various capacities; aged 60; died, April 26, in the Quincy (Mass.) Hospital of cerebral hemorrhage.

Robert Bernard Gaston, Lebanon, Tenn.; Vanderbilt University School of Medicine, Nashville, 1912; member of the Tennessee State Medical Association; fellow of the American College of Surgeons; secretary of the Wilson County Medical Society; past president of the Middle Tennessee Medical Association; formerly owner and medical superintendent of the Martha Gaston Hospital; aged 53; died, April 16, at the Vanderbilt Hospital, Nashville.

Arthur Rufus Trego Wylie, Faribault, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1906; member of the American Psychiatric Association; at one time superintendent of the North Dakota State Institution for the Feeble-minded, Grafton, N. D.; on the staff of the Minnesota School for Feeble-minded; aged 69; died, March 30, of glomerular nephritis, uremia and coronary thrombosis.

Jacob Paul Frantz, Clearfield, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1910; member of the American College of Chest Physicians; secretary of the Clearfield County Medical Society; for many years president of the city board of health; president of the Clearfield County Tuberculosis Society; on the staff of the Clearfield Hospital; aged 55; died, April 8, of nephritis.

Jacob Allen Stout, Bexley, Ohio; Starling Medical College, Columbus, 1889; member of the Ohio State Medical Association; formerly examining physician for the county court of domestic relations; for many years on the staff of St. Anthony Hospital and St. Ann's Infant Asylum and Maternity Hospital, Columbus; aged 78; died, March 30, of coronary embolism.

James William Robinson, Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1907; associate professor of surgery, University of Pittsburgh School of Medicine; served during the World War; aged 56; on the staffs of the Roselia Foundling and Maternity Hospital and the Mercy Hospital, where he died, March 23, of disease of the coronary artery.

Charles W. Holland, Scottsville, Ky.; University of Tennessee Medical Department, Nashville, 1896; member of the Kentucky State Medical Association; past president of the Allen County Medical Society; for many years health officer of Allen County; formerly member of the board of education; bank president; aged 68; died, April 24, of coronary occlusion.

George William Conrad, Johnstown, Pa.; Eclectic Medical Institute, Cincinnati, 1905; member of the Medical Society of the State of Pennsylvania; served during the World War; formerly chief medical examiner for the United States Pension Service; aged 61; died, April 6, in the Memorial Hospital of hypertension, uremia and nephrosclerosis.

Judson Frederick Browne, Rochester, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1907; member of the Medical Society of the State of New York; served during the World War; aged 59; died, April 5, in the Veterans Administration Facility, Batavia, of cerebral thrombosis following suprapubic prostatectomy.

Joseph Spangenthal @ Buffalo; University of Louisville (Ky.) Medical Department, 1892; University of Buffalo School of Medicine, 1896; at one time associate professor of dermatology at the University of Buffalo School of Medicine; aged 71; died, March 30, of hypostatic pneumonia, arteriosclerosis and diabetes mellitus.

Walter McDonald Davidson, Port Angeles, Wash.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1923; member of the Washington State Medical Association; aged 47; died, March 25, in a hospital at Seattle of duodenal ulcer, abscess of the neck with staphylococcal septicemia and cirrhosis of the liver.

Edward West Hollingsworth @ Chicago; University of Virginia Department of Medicine, Charlottesville, 1918; member of the Central Society for Clinical Research; fellow of the American College of Physicians; on the staff of the Veterans Administration Facility, Hines; aged 47; died, March 15, of coronary thrombosis.

Frank Ferrell, Ashland, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1898; member of the Mississippi State Medical Association; president of the North Mississippi Medical Society; county health officer; aged 71; died, March 31, in Oxford, of glandular carcinoma of the cecum.

Carr Thomas Dowell Jr., Baton Rouge, La.; University of Oklahoma School of Medicine, Oklahoma City, 1929; member of the Louisiana State Medical Society; first lieutenant in the medical reserve corps of the United States Army; aged 35; died, March 25, of acute dilatation of the heart.

Thomas Jennings, Clinton, Tenn.; University of Tennessee Medical Department, Nashville, 1909; member of the Tennessee State Medical Association; served during the World War; aged 57; died, March 31, in St. Mary's Hospital, Knoxville, of injuries received in an automobile accident.

Daniel Crosby Greene @ Newton, Mass.; Harvard Medical School, Boston, 1899; member of the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; at one time instructor in laryngology at his alma mater; aged 68; died, April 4.

Valentine Ruch, Englewood, N. J.; Cornell University Medical College, New York, 1903; member of the Medical Society of New Jersey; on the staffs of the Englewood Hospital, and the Holy Name Hospital, Teaneck; aged 65; died, March 30, of coronary occlusion.

Alexander L. Johnson, Gloversville, N. Y.; Albany Medical College, 1885; member of the Medical Society of the State of New York; on the staff of the Nathan Littauer Hospital; aged 79; died, February 27, of carcinoma of the larynx and acute dilatation of the heart.

Edwin Nelson Cleaves, Boston; Harvard Medical School, Boston, 1915; member of the Massachusetts Medical Society, American Roentgen Ray Society, New England Roentgen Ray Society and the American College of Radiology; aged 50; died, February 23.

James P. Widmeyer @ Rolla, N. D.; College of Physicians and Surgeons of Chicago, 1896; formerly mayor; chairman of the county board of health; at one time superintendent of the State Tuberculosis Sanatorium, San Haven; aged 72; died, March 17.

Crayton C. Fargason, Dadeville, Ala.; Atlanta (Ga.) College of Physicians and Surgeons, 1904; member of the Medical Association of the State of Alabama; county health officer; aged 66; died, March 30, in the Community Hospital, East Tallahassee.

Joseph Bakst @ New York; Columbia University College of Physicians and Surgeons, New York, 1906; on the staff of the Jewish Maternity Hospital; aged 72; died, April 13, in the Beth Israel Hospital, of arteriosclerosis, heart disease and pneumonia.

Austin E. Miller, McAllen, Texas; College of Physicians and Surgeons of Chicago, 1895; member of the Colorado State Medical Society; aged 75; died, February 21, in the McAllen Municipal Hospital of ruptured aneurysm of abdominal aorta.

William Anderson Royer, Battle Creek, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; member of the Michigan State Medical Society; aged 76; died, March 30, of cerebral thrombosis.

Edgar Francis Smith, Storm Lake, Iowa; State University of Iowa College of Medicine, Iowa City, 1908; member of the Iowa State Medical Society; formerly health officer; aged 67; died, March 8, of acute myocarditis.

Herbert Carl Goetz, Buffalo, University of Buffalo School of Medicine, 1919; member of the Medical Society of the State of New York; on the staff of the Deaconess Hospital; aged 46; died, April 8, of coronary occlusion.

Herbert Livingston Scales @ Hutchinson, Kan.; Louisville (Ky.) Medical College, 1892; member of the American Academy of Ophthalmology and Otolaryngology; aged 71; died, March 28, of cerebral hemorrhage.

Edward Patrick D. Donohue, Syracuse, N. Y.; Syracuse University College of Medicine, 1916; on the staff of St. Joseph's Hospital; aged 55; died, March 26, of arteriosclerosis, heart disease and diabetes mellitus.

William Watson Ayres, Washington, D. C.; Columbian University Medical Department, Washington, 1890; aged 73; died, February 10, in the Emergency Hospital of coronary thrombosis and lobar pneumonia.

Harold E. Pratt, San Pedro, Calif.; College of Medical Evangelists, Los Angeles, 1939; first lieutenant in the medical reserve corps of the United States Army; aged 31; was killed, April 3, in an airplane accident.

Ernest Lazarus Booth, East Boston, Mass.; Harvard Medical School, Boston, 1908; member of the Massachusetts Medical Society; for many years school physician; aged 56; died, March 24, of pneumonia.

Maxwell Nathaniel Frank @ Detroit; Detroit College of Medicine and Surgery, 1917; aged 47; died, April 1, in Miami Beach, Fla., of injuries received in an automobile accident several months previously.

Richard R. Elmore @ Louisville, Ky.; Hahnemann Medical College and Hospital, Chicago, 1903; University of Louisville Medical Department, 1904; aged 63; died, March 28, of a self-inflicted bullet wound.

Frank Glynn Young, Brooklyn; New York Homeopathic Medical College and Hospital, New York, 1906; aged 59; died, March 25, in the Veterans Administration Facility, Northport, of coronary occlusion.

Lawrence Stevens @ Billings, Mont.; University Medical College of Kansas City, Mo., 1910; served during the World War; aged 59; died, March 23, in San Diego, Calif., of coronary heart disease.

William Clemens Davis, Smithland, Ky.; Hospital College of Medicine, Louisville, 1902; member of the Kentucky State Medical Association; aged 69; died, March 30, of cerebral hemorrhage.

William J. L. Roberts, Chapel Hill, Texas; University of Texas School of Medicine, Galveston, 1904; member of the State Medical Association of Texas; aged 63; died, February 7, of heart disease.

Oren Brown Richards Jr. @ Moosic, Pa.; University of Rochester (N. Y.) School of Medicine and Dentistry, 1935; aged 29; died suddenly, March 31, of accidental carbon monoxide poisoning.

Lester Edwin Hackbarth @ Toledo, Ohio; State University of Iowa College of Medicine, Iowa City, 1927; on the staff of the Toledo Hospital; aged 42; died, March 31, in an automobile accident.

William E. Catterson, Noblesville, Ind.; Physio-Medical College of Indiana, Indianapolis, 1906; member of the Indiana State Medical Association; aged 78; died, April 6, of Parkinson's disease.

Edward Barton Jones, McLean, Va.; Columbian University Medical Department, Washington, D. C., 1902; served during the World War; aged 74; died, March 8, of coronary thrombosis.

Gustave Lewis, Seattle; University of Bishop College Faculty of Medicine, Montreal, Que., Canada, 1895; member of the Washington State Medical Association; aged 67; died, March 3.

Russell Stewart Bacon @ Montevideo, Minn.; Rush Medical College, Chicago; 1885; an Affiliate Fellow of the American Medical Association; aged 81; died, March 30, of cirrhosis of the liver.

Edward Malcom Hoyt, Georgetown, Mass.; Harvard Medical School, Boston, 1894; member of the Massachusetts Medical Society; aged 83; died, March 28, of coronary heart disease.

William Victor Watson, Redondo Beach, Calif.; Columbus (Ohio) Medical College, 1891; member of the Colorado State Medical Society; aged 77; died, March 27, of cerebral hemorrhage.

John Knotz, Cologne, Minn.; Minneapolis College of Physicians and Surgeons, Minneapolis, 1897; aged 68; died, March 31, of cerebral hemorrhage, arteriosclerosis and diabetes mellitus.

William J. Robinson, Portia, Ark.; Memphis (Tenn.) Hospital Medical College, 1897; member of the Arkansas Medical Society; aged 76; died, March 11, of chronic nephritis.

Marie Meirovna Kovner Ramme, Washington, D. C.; Second Moscow Medical Institute, Moscow, Russia, R. S. F. S. R., 1921; aged 46; died, March 12, of cerebral hemorrhage.

D. J. Dunkelmann, Clarence, La.; Hospital College of Medicine, Louisville, Ky., 1907; member of the Louisiana State Medical Society; aged 58; died, February 15, of hypertension.

Julian N. Mincey @ Mineral Wells, Texas; University of Texas School of Medicine, Galveston, 1899; aged 72; died, March 24, in the Nazareth Hospital of cerebral embolism.

Charles A. Barlow, St. Petersburg, Fla.; Baltimore Medical College; 1896; aged 66; died, April 11, in the Veterans Administration Facility, Bay Pines, of coronary occlusion.

Walter Noble, Aransas Pass, Texas; Tulane University School of Medicine, New Orleans, 1904; member of the State Medical Association of Texas; aged 64; died, March 27.

Edgar Ardis Peterson, Baltimore; Vanderbilt University School of Medicine, Nashville, Tenn., 1902; aged 59; died, March 29, of burns received when his home caught fire.

Hugh Peavler, Mount Vernon, Ill.; University of Tennessee Medical Department, Nashville, 1885; aged 76; died, March 29, of valvular heart disease and arteriosclerosis.

Abram C. Cluts, Prairie City, Ill.; Rush Medical College, Chicago, 1893; aged 73; died, March 31, in the Graham Hospital, Canton, of uremia and hypertrophy of the prostate.

Robert T. S. Steele, Williamsport, Pa.; University of Maryland School of Medicine, Baltimore, 1899; aged 67; died, March 5, in Fort Pierce, Fla., of cerebral hemorrhage.

Thomas Francis Godfrey, Springfield, Mass.; College of Physicians and Surgeons, Baltimore, 1898; aged 68; died, April 2, in the Mercy Hospital of chronic pyelonephritis.

Thomas M. Merritt, Americus, Ga.; College of Physicians and Surgeons, Baltimore, 1891; aged 77; died, March 30, of edema of the lungs and fracture of the left hip.

William Moore, New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1884; aged 79; died, March 20, of pneumonia.

George Washington Mixon, Watson, La.; Memphis (Tenn.) Hospital Medical College, 1894; parish health officer; aged 77; died, March 23, of gastric carcinoma.

Elizabeth Bailey Muncey, Washington, D. C.; Howard University College of Medicine, Washington, 1898; aged 83; died, March 9, of illuminating gas poisoning.

Arthur John Ochs, Oak Park, Ill.; Chicago College of Medicine and Surgery, 1915; member of the Illinois State Medical Society; aged 55; died, March 29.

George L. Wimberley Jr., Rocky Mount, N. C.; University of Maryland School of Medicine, Baltimore, 1883; aged 79; died, March 22, of cerebral hemorrhage.

Paul Jones Flory @ Pawnee City, Neb.; University of Nebraska College of Medicine, Omaha, 1916; aged 51; died, March 4, of carbon monoxide poisoning.

William N. Gray, Celina, Tenn.; University of Tennessee Medical Department, Nashville, 1889; aged 81; died, March 31, in Nashville of cerebral hemorrhage.

Hubert B. Strong, Tyre, N. Y.; Detroit College of Medicine, 1892; aged 75; died, February 9, of diabetes mellitus, cerebral embolism and arteriosclerosis.

William E. Busby, San Diego, Calif.; National Medical University, Chicago, 1906; also a dentist; aged 74; died, February 12, of cerebral hemorrhage.

Franklin Filmore Marsh, De Land, Fla.; Hahnemann Medical College of Philadelphia, 1880; aged 88; died, March 20, of pneumonia, following influenza.

Rufus C. McGahey, Miami, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1878; aged 83; died, March 9, of bronchopneumonia.

John Thomas Maloney, Tuba City, Ariz.; Long Island College Hospital, Brooklyn, 1928; member of the Indian Service; aged 39; died, March 5.

George F. Kelly, Los Angeles; Columbian Medical College, Kansas City, Mo., 1901; also a dentist; aged 73; died, February 20, of heart disease.

Benjamin Hardy Carlton, Freeport, Texas; University of Tennessee Medical Department, Nashville, 1888; aged 79; died, February 7, of influenza.

Gedeon Des Rosiers, St. Felix de Valois, Que., Canada; Victoria University Medical Department, Coburg, Ont., 1873; aged 93; died, February 15.

Isaac N. Barnett, Kansas City, Mo.; Washington University School of Medicine, St. Louis, 1897; aged 68; died, April 4, of cerebral hemorrhage.

George W. Brown, Lawtey, Fla.; University of Maryland School of Medicine, Baltimore, 1889; aged 74; died, April 2, of coronary occlusion.

John W. Fawcett, McKeesport, Pa.; Jefferson Medical College of Philadelphia, 1877; aged 87; died, March 2, of cerebral hemorrhage.

Morris Rosentover, New York; Bellevue Hospital Medical College, New York, 1897; aged 67; died, March 30, of carcinoma of the liver.

Alice Winans Downey, Washington, D. C.; George Washington University School of Medicine, Washington, 1911; aged 77; died, March 9.

John W. Robertson, San Francisco, Calif.; University of California Medical Department, San Francisco, 1880; aged 84; died, February 28.

Theodore Alexandre Talbot, St. Felicien, Que., Canada; Laval University Faculty of Medicine, Quebec, 1874; aged 82; died, February 12.

Sandford Barto Henton, Decatur, Miss.; Medical College of Alabama, Mobile, 1887; aged 79; died, March 31, of nephritis and heart disease.

Hugh McLean Scott, Morriston, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1929; aged 36; died in February.

Joseph Ludger Gagnon, Montmagny, Que., Canada; Laval University Faculty of Medicine, Quebec, 1912; aged 54; died, February 10.

Cyrillus Wirth, Davenport, Iowa; College of Physicians and Surgeons, Keokuk, 1893; aged 71; died, March 19, of heart disease.

Louis Auguste Bourbeau, Rouyn, Que., Canada; Laval University Faculty of Medicine, Quebec, 1928; aged 39; died, February 6.

John McGovern, Wisconsin Dells, Wis.; Northwestern University Medical School, Chicago, 1906; aged 69; died, March 13.

Maria F. Spiess Schaltenbrandt, San Francisco; California Medical College, San Francisco, 1895; aged 81; died, February 26.

Nelson J. Shook, Corunna, Ind.; Miami Medical College, Cincinnati, 1890; aged 80; died, March 31, of cerebral hemorrhage.

Irving Muscanto, Brookline, Mass.; Tufts College Medical School, Boston, 1934; aged 33; hanged himself, February 12.

Joseph J. Nimschik, Chicago; Chicago College of Medicine and Surgery, 1914; aged 66; died, February 21.

Frank E. Keep, Los Angeles; Cleveland Medical College, 1897; aged 66; died, February 5, of fractured pelvis.

Albert Henry Lilley, Long Beach, Calif.; Harvard Medical School, Boston, 1902; aged 62; died, February 14.

Takejiro Itow, Los Angeles; Keio Gijuku University Medical College, Tokyo, Japan, 1897; died, March 2.

Hubert Joseph Williams, Boston; Tufts College Medical School, Boston, 1901; aged 61; died, March 29.

Charles Pollack, Brooklyn; College of Physicians and Surgeons, Boston, 1906; died, March 21.

Robert S. Foster, Carolan, Ark. (licensed in Arkansas in 1903); aged 72; died, March 9.

Bureau of Investigation

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission, in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 added to the Food and Drug Administration's control of the advertising claims and statements made on the labels of medicines or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission, by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection, even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual, manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable.

Abstracts of some of the orders issued during 1940 follow:

Air Conditioning Soap.—This product, also designated as "Air Conditioning the Human Body" soap, is or was put out by Air Conditioning Textiles, Inc., New York. On Aug. 23, 1940, the Federal Trade Commission ordered this concern to cease and desist from using the words "air conditioning" or any other similar term to describe its soap or from otherwise representing that this soap possesses air conditioning properties, that it reduces body temperature or humidity or eliminates perspiratory conditions or that the human body breathes through the pores of the skin.

Ardanol, Chloro-Zol and Germ-I-Tabs.—These are products of the American Drug and Chemical Company, Minneapolis. On Sept. 26, 1940, this concern was ordered by the Federal Trade Commission to cease and desist from making certain misrepresentations in its advertising. Among these were that "Ardanol," promoted for use in cases of vitamin E deficiency, is a cure or remedy for sterility or will restore or beneficially affect fertility or possesses any value as a preventive of abortion; that the preparations "Chloro-Zol" and "Germ-I-Tabs" constitute competent or effective antiseptics or germicides or a reliable or effective means of feminine hygiene, and that Chloro-Zol constitutes a competent or effective treatment for bromidrosis, tetter, itching and irritations of the skin, blisters on the feet, acne, boils, halitosis or body odors. The Commission's findings were that the respondent's products do not generally accomplish the results claimed and that, while Chloro-Zol and Germ-I-Tabs possess antiseptic properties of a low toxicity, they are not competent or effective antiseptics or germicides.

Brewster Nostrums.—Jefferson R. Brewster of Nashville, Tenn., has at different times run afoul of three government agencies—the Food and Drug Administration, the Federal Trade Commission and the Post Office Department. The last named has on three occasions issued fraud orders against Brewster and his trade names, debarring them from the use of the mails. The Food and Drug Administration once prosecuted him for making fraudulent claims on his labels, but unfortunately a jury in a district federal court brought in a verdict of not guilty. In 1938 the Federal Trade Commission commenced action against the Brewster outfit (then at Dallas, Texas) because of the false claims made for the Brewster nostrums as alleged remedies for cancer, asthma, tuberculous hemorrhages, pneumonia, diphtheria, gallstones, goiter and some other things. All these actions were discussed in THE JOURNAL, July 13, 1940, page 149. On July 16, 1940, the Federal Trade Commission reported that it had definitely ordered Jefferson R. Brewster, trading as Brewster Laboratories, and "Dr." Reece Brewster, Nashville, to cease making certain misrepresentations in the sale of his products sold under the Brewster brand, such as the "Tonic," "G-D," "T-Z," "Throat Wash," "Throat-Eaz," "Sinine," "Pain Kill," "Ready Relief" and "Pile Ointment." Among the misrepresentations were that these nostrums variously possess therapeutic value in the treatment of such conditions as tuberculosis, constipation, hemorrhages, nervousness, sinus and mastoid disorders, rheumatism, typhoid, cancer, gallstones, goiter and sciatia. Brewster also was ordered to cease using the word "Laboratories" in his trade name.

Dr. Pierre's Boro-Pheno-Form Vaginal Suppositories.—This product and "Dr. Pierre's Boro-Pheno-Form Vaginal Creme" are put out by the Dr. Pierre Chemical Company of Chicago, which represented them as effective germicides and preventives of conception and as possessing substantial therapeutic agents which heal irritated tissues and membranes. On Oct. 5, 1940, the Federal Trade Commission ordered this concern to discontinue these practices and to cease representing that any substantial number of reputable physicians has approved or recommended the products.

Glantex.—Advertising this product as a cure or a safe and effective treatment for prostatitis, cystitis, urethritis, sugar diabetes, dropsy, gastritis, malaria, ptomaine poisoning, rheumatism and some other things, George G. Neff, trading as the Prostex Company, Miami, Okla., was ordered by the Federal Trade Commission on July 22, 1940, to discontinue such misrepresentations and also to cease promoting the preparation as having any therapeutic value in excess of its laxative properties.

Grove Laboratories, Inc.—This St. Louis concern was ordered by the Federal Trade Commission on July 13, 1940, to cease representing that its "Pazo Ointment" is a cure or remedy for hemorrhoids or has any value in treating them aside from affording palliative relief in cases of simple hemorrhoids. The company was further ordered to discontinue representing that "Dr. Porter's Antiseptic Healing Oil" is an effective or standard treatment for cutaneous diseases caused by infection; that it is a competent agent in the treatment of dandruff, falling hair or diseases peculiar to the scalp; that it will promote the growth of hair, prevent baldness or destroy parasites usually associated with dandruff and other diseases of the scalp.

Harmless Prescription Capsules.—These bore the firm name of Sun Cut Rate Store, Huntington, W. Va., a trade style for Howard Deckelbaum, who also sold them under the names "Special Prescription Capsules" and "Prescription Female Capsules." The latter was designated as "double strength" or "triple strength." On Oct. 25, 1940, the Federal Trade Commission ordered Deckelbaum to discontinue advertisements representing that his preparation is a competent or effective treatment for delayed menstruation and that it is safe or harmless; or advertisements which fail to reveal that use of the preparation may cause gastrointestinal disturbances and excessive congestion and hemorrhage of the pelvic organs, and, in the case of pregnancy, may cause uterine infection and blood poisoning.

Hot Springs Mineral Soap.—This was one of the products put out by Lawrence L. Keller of Seattle, who did business as the United Soap Company. On July 18, 1940, the Federal Trade Commission ordered him to cease representing that soaps he sells under the brand names "Hot Springs Mineral Soap," "Hawaiian Rose," "Velvette" and some similar designations, are imported or are manufactured in any other place than Seattle, that they are "vitaminized" or medicated in any way, or have medicinal or curative value or are in any manner more beneficial than any ordinary toilet soap.

Hydrosal Products.—The Hydrosal Company of Cincinnati puts out "Hydrosal Liquid" and "Hydrosal Ointment." On June 3, 1940, the Federal Trade Commission ordered the company to cease representing in its advertisements that these nostrums possess curative or healing properties in the treatment of eczema, piles, athlete's foot, poison ivy or disorders characterized by or associated with pimples, cutaneous outbreaks or itches. The order also prohibited, among other things, the representation that the products named are in general use by the medical profession or hospitals.

O. B. C. Capsules.—This nostrum, also known as "O. B. C. Reducing Capsules," is put out by I. Ralph Weinstein, trading as Thyrole Products Company, Philadelphia. On Nov. 26, 1940, the Federal Trade Commission ordered this concern to cease representing that the product is a cure, remedy or a competent, safe or effective treatment for obesity. The order also prohibits the dissemination of advertisements failing to reveal that use of the preparation may cause permanent injury to the heart, thyroid gland and other vital organs. The Commission declared that the nostrum will not accomplish the results claimed and is not safe to use, because the stuff contained such drugs as strychnine alkaloid, extract of belladonna, aloin, phenolphthalein and thyroid in quantities sufficient to cause serious and irreparable injury to health if used under conditions prescribed in the advertisements or under customary or usual conditions. Another federal agency, the Food and Drug Administration, had already taken action against the same Philadelphia concern, declaring that because of the thyroid and phenolphthalein content found in a shipment of O. B. C. Capsules seized in interstate commerce, these would be dangerous to health when used in the dosage or with the frequency prescribed on the labeling. As the company put up no defense, the consignment in question was ordered confiscated in May 1939.

Plat-Num Perl Products.—These were put out by a New York concern operated by A. Sartorius and Company, Inc., using the trade style "Plat-Num Perl Laboratories." It was ordered by the Federal Trade Commission on Dec. 20, 1940, to discontinue certain false and misleading representations in its advertising. Among these were that its "Plat-Num Oil Compound Nail Polish Remover" contains enough olive oil to justify the name and that it would relieve or improve to any appreciable extent the condition of dry, brittle nails; or that its "Plat-Num Nail Protector" encourages nail growth or strengthens the nails, whereas it does nothing of the sort. The concern was further ordered to discontinue using the words "olive oil" or any similar designation.

Urine.—This product of the Aurine Company, Inc., of Chicago, was formerly sold as "Aurine." On July 1, 1940, the Federal Trade Commission ordered the concern to cease advertising that the preparation is a cure, remedy or competent or effective treatment for complete or partial deafness; that it possesses any therapeutic value in excess of such aid as it may render in softening coagulated wax in the ear, and that the company makes refunds to dissatisfied purchasers, when in fact it does not maintain a definite policy of making such refunds. In December 1937 the Food and Drug Administration at Washington declared that a shipment of "Urine Application for the Ears," which had been seized in interstate commerce, was fraudulently represented as a remedy for ear troubles. Government chemists reported in this connection that they had found it to be essentially a mixture of glycerin, boric acid, extracts of plant drugs and volatile oils including lavender.

Council on Medical Education and Hospitals

SUMMARY OF ELIGIBILITY REQUIREMENTS OF CERTIFYING BOARDS

B. R. KIRKLIN, M.D.
Secretary American Board of Radiology
ROCHESTER, MINN.

The task assigned me was to study the requirements for eligibility of candidates for examination and certification as prescribed by the various special boards and to discuss reasons for divergences of these requirements from those recommended by the Advisory Board for Medical Specialties. Accordingly, to make comparison easy, I have tabulated the eligibility requirements listed by the several boards, including not only items concerning which the Advisory Board has offered advice but also those about which it has made no recommendations. In discussing them we should remind ourselves that the recommendations of the Advisory Board are not binding; that some of them need not be complied with before Jan. 1, 1942; that some of the special boards existed and had formulated their rules before the Advisory Board was established; that certain of this board's recommendations have been broadly expressed, leaving considerable latitude for substantial conformity to them; that as to requirements not dealt with by this board the special boards have been free to exercise their judgment, and that each specialty has to consider its own peculiar problems and circumstances.

It is not surprising, then, that there are differences among special boards as to eligibility requirements and divergences from recommendations of the Advisory Board, but it must also be said that the extent of agreement is both surprising and gratifying. At all events, analysis and discussion of the facts may bring out constructive criticism and helpful action by this board. In whatever we do we shall, of course, have to keep in mind the two basic aims of special boards, namely to forestall examination of those who are morally and ethically unfit and certification of those who are incompetent and, at the same time, to avoid demanding unreasonable requirements of applicants who are competent. These aims are equally important, and neither should be promoted by unduly sacrificing the other.

In going over this tabulation I shall express my own opinions freely, sometimes rather positively, not at all because I am confident that I know the answer but because I hope to provoke an equally frank expression of different views.

GENERAL REQUIREMENTS

Fees.—Seven boards have set the examination fee at \$50, four at \$75, one at \$30, two at \$35 and one at \$100. The average fee charged is \$56.66. For reexamination, three boards require a fee of \$10 and one board requires \$15. One board reduces the fee for the second application from \$50 to \$35. All other boards allow the candidate a second examination without further fee, but he must pay the full fee for subsequent applications.

In fixing fees it is proper to consider the number of practitioners in a specialty, the probable number of yearly recruits, the expenses to be allowed members of the boards, the expense of maintaining headquarters, and the building up of a reasonable reserve for later and perhaps leaner years. These and other factors vary widely among the specialties, and I have no further comment to make regarding fees.

Membership in American Medical Association.—All boards except one require membership in the American Medical Association, the Canadian Medical Association or a society recognized by the Council on Medical Education and Hospitals of the American Medical Association. Thus these boards are in accord with the recommendation of the Advisory Board. The exception is the Board of Pediatrics, which exacts no requirement in this respect. The Advisory Board has provided that

exceptions to this requirement may be made by any individual board for good and sufficient reasons.

License to Practice.—Eight boards require the applicant to be licensed to practice medicine. Seven boards do not list this requirement in their booklet.

Limitation of Practice.—Three boards specify that 100 per cent of the applicant's practice shall be devoted to his specialty. The Board of Obstetrics and Gynecology requires that 100 per cent of the applicant's practice shall be restricted to females. Eligible applicants may do a certain amount of urology, general abdominal surgery or even breast surgery so long as it is all done on female patients. The Board of Neurosurgery requires that 100 per cent of the applicant's practice shall be devoted solely to that specialty alone or in combination with neurodiagnosis. Otolaryngology demands 90 per cent, but ophthalmology may be included in this figure. Psychiatry and Neurology says that limitation need not be complete if the applicant can prove his competence. Radiology uses the phrase "substantial portion of his practice" and at present interprets that to mean not less than 70 per cent. Pathology interprets its words "primarily and principally" to mean not less than 70 per cent. Urology demands only assurance by the applicant that he is engaged in the practice of urology and will so continue. Other boards have no ironclad requirement in this respect.

Concerning this requirement I have some strong opinions. It is reasonable to require the applicant to devote a "substantial portion" of his time, effort and interest to the practice of a specialty or even to practice it "primarily and principally." Otherwise he would seem to have little reason for desiring certification, and his motive for applying would be open to question. But I feel that the requirement of 100 per cent is excessive and unfair. It bars candidates who may be competently practicing a specialty in smaller communities, hospitals, groups and institutions and who are obliged to give part time service in other fields. It also bars any competent aspirant whose special practice is not as yet sufficiently remunerative, obliging him to do other work in addition, but who expects to confine himself to his special field as soon as his practice will support him and hopes that certification will help to increase the amount of his special work. In short, I feel that the competence of the candidate, as determined by examination, is the essential test of his fitness for certification and that if the major portion of his practice is in his special field he should be deemed eligible for examination. Eligibility requirements are proper and desirable, for they avert useless examinations, but they should be construed with the utmost fairness to the applicant, and no board should lay itself open to the accusation that it declines to examine applicants whose practice is not limited exclusively to the specialty even though they prove themselves to be competent.

Case Reports.—The Board of Ophthalmology requires ten case reports by the applicant, and fifty are required by Obstetrics and Gynecology and Urology. No other board demands case reports. I have no comment to offer regarding this requirement.

PROFESSIONAL EDUCATION

Medical School.—All boards except Pediatrics require the applicants to be graduates of a medical school approved by the Council on Medical Education and Hospitals. Obstetrics and Gynecology requires approval also by the Advisory Board. The Board of Pediatrics requires a school approved only by that board. As to applicants educated in foreign schools, Surgery, Anesthesiology and Plastic Surgery say that the school must be "approved" but do not say by whom; Internal Medicine, that their credentials must be acceptable to the Council on Medical Education and Hospitals, Advisory Board and National Board of Medical Examiners; Neurosurgery, a school acceptable to that board; Ophthalmology, a school approved by that board and "he may be required to obtain the certificate of the National Board of Medical Examiners"; Urology, that the applicant must be licensed to practice and have a certificate from the National Board of Medical Examiners; Pathology, that their credentials must be acceptable to the National Board of Medical Examiners and the American Board of Pathology, and Radiology that their credentials must be satisfactory to the Advisory Board.

From the Section on Roentgenology, the Mayo Clinic.
Read at Round Table Discussion, Advisory Board for Medical Specialties, Chicago, Feb. 16, 1941.

It would seem at first glance that there is a lack of uniformity in dealing with those candidates who graduate from foreign medical schools. I doubt very much that any one of the boards or even the Advisory Board has a list of approved foreign medical schools. All the boards have one common purpose in dealing with applicants who graduate from foreign schools, namely to make certain that they have had adequate medical preparation. It seems to me therefore that, rather than leave it to the judgment of the Advisory Board or of the individual board, it would be much better to require all those who have graduated from foreign medical schools to obtain the certificate of the National Board of Medical Examiners before being admitted to the examination of a special board.

Internship.—An internship of one year is required by all boards. Three boards require a general rotating internship; one board calls for either a rotating internship or a straight internship in any branch of medicine; another requires a straight surgical internship or its equivalent in the opinion of the board. Other boards do not specify the character of the services. In my opinion a rotating internship is desirable, because it furnishes a broad foundation.

SPECIAL TRAINING

Graduate Training.—Two boards (Surgery and Plastic Surgery) demand a graduate training period of five years, although

and Pathology say nothing regarding basic science requirements. Otolaryngology says merely that the candidate must have completed an acceptable course in the basic sciences. Radiology, the only specialty that speaks in terms of time, requires that the applicant devote six months of his three year training to pathology. All other boards require the candidate to have knowledge of the basic sciences, particularly as related to the individual specialty, but do not prescribe time or manner of instruction.

Recently, I understand, it has been rumored that instruction for a year and a half in the basic sciences, during the minimal three year training period, would be recommended by the Advisory Board. I have no knowledge of any such intention and I am not sympathetic toward the idea. As all applicants must be graduates in medicine, all of them must have had instruction in the basic sciences and I can see no reason at all for requiring graduate students to spend a year and a half of their special training in reviewing these fundamentals. On the other hand, I consider it highly desirable, if not imperative, for the student to refresh and enlarge his knowledge of the basic sciences related to his intended specialty. This brings up the problem of how and how long this instruction shall be given. For my part, I am opposed to demanding formal and exclusive instruction for a year or longer. Most of the instruction in the basic sciences, with the possible exception of pathology, can be given along with the clinical training. Concerning the

Plastic Surgery¹ requires that only two years of that time be devoted exclusively to plastic surgery. Ophthalmology and Otolaryngology in combination also require five years. Nine specialties require three years of formal graduate training. Two boards (Pediatrics and Anesthesiology) set the minimal period at two years, and one board (Otolaryngology) prescribes a residency of only one year but recommends two in addition to "an acceptable basic science course." It will be noted that the latter three boards do not as yet require full three years graduate training recommended by the Advisory Board.

The Advisory Board has never intended to regiment the component boards by requiring that uniform graduate training be generally adopted. The question of adequate training in each of the specialties can best be determined within certain limitations by the respective boards. It seems reasonable that for those specialties covering limited anatomic fields or procedures a shorter period of training might be adequate. On the other hand, boards covering wide fields should exercise caution lest they demand a period of special training that is too long as well as too rigid.

Basic Sciences.—The Advisory Board as well as most of the fifteen examining boards recommend "graduate training in anatomy, physiology, pathology and the other basic medical sciences which are necessary to the proper understanding of the specialty," but only one board specifies the amount of time that shall be devoted to one of the basic sciences. Pediatrics

manner of instruction, the American Board of Internal Medicine offers a liberal and commendable program.² In short, I would leave things pretty much as they are.

Clinical Training.—"An active experience of not less than eighteen months in hospital clinics, dispensaries and diagnostic laboratories" is recommended by the Advisory Board. Training time to be applied to the clinical and practical aspects of the specialty is set at four years by the Board of Surgery. Radiology prescribes two and a half years. Pathology requires three years. Pediatrics, Orthopaedic Surgery and Plastic Surgery require two; Otolaryngology, one to two; Dermatology and Syphilology and Urology, each one and a half years. Ophthalmology, Obstetrics and Gynecology, Psychiatry and Neurology, Internal Medicine, Anesthesiology and Neurosurgery apparently do not prescribe any specific allotment of time to be spent in clinical training.

Here again I think that the individual boards are better able to determine the minimal time that should be devoted to the clinical aspects of the respective specialties.

Additional Period.—Two years' additional practice after the formal training period are prescribed by nine boards; one to one and a half years by Otolaryngology and one by Pathology. One board (Obstetrics and Gynecology) after March 1, 1942 will require four years. Four boards (Ophthalmology, Radiology, Surgery and Plastic Surgery) have no requirement in this respect. Orthopaedic Surgery alone of all the boards demands that the required additional two years be spent in private practice. All other boards, requiring time in addition

1. The American Board of Plastic Surgery was, at the time these data were collected, an affiliate board of the American Board of Surgery. It will soon be an independent board and will, no doubt, change this requirement.

2. See 1938 booklet, pp. 7-9.

to the formal training, permit the applicant to spend this time either by remaining for further training or as an assistant, or by devoting the time to private practice.

The requirement of a certain number of years in private practice is advantageous in that it gives the special board an opportunity to appraise the candidate's professional integrity as a private practitioner.

In this connection it may be interesting to summarize the length of time that must be spent by the applicant following his internship before he is eligible for examination. The following figures cover the graduate training period plus additional time when demanded: Total time for three of the boards (Ophthalmology, Otolaryngology and Radiology) is three years, and for three of the boards (Pediatrics, Pathology and Anesthesiology) the time is four years. For the remaining nine boards the time is five years. It should be noted also that, if the candidate is applying for both psychiatry and neurology, six years must elapse, and that after March 1, 1942 one board (Obstetrics and Gynecology) will require a total period of seven years.

It has already been stated that one board (Orthopedic Surgery) which requires a total of five years to elapse demands that two years of this time be devoted to private practice without supervision. In contrast, another board (Surgery) which likewise requires a period of five years to elapse does not permit any of this time to be given to private practice without supervision.

My net impression from this review is that, while there are a few instances in which certain requirements are perhaps rather lax, there are more instances in which the conditions for eligibility are unnecessarily stringent. These conditions might be defended on the ground that they are designed to raise standards of practice. I am sure that we all endorse this aim in principle and that all of us cherish high ideals, but we also have to consider the practical side and must avoid trying to force achievement of those ideals too rapidly. Unduly severe requirements seem to reflect the spirit of the guild and to suggest a desire to restrict the number of recruits in a specialty. Now we know that the boards have no such wish, but in our zeal to keep out incompetents we must not overlook the other duty—that of fostering certification of applicants who are really competent. At all events, our primary job is to certify those, and only those, who are competent.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS

EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in *THE JOURNAL*, May 31, page 256.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 17-19. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: Phoenix, July 1-2. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, July 14. Written. San Francisco, June 30-July 3. Sec., Dr. Charles B. Pinkham, 1020 N St., Sacramento.

COLORADO: Denver, July 18. Applications must be on file not later than June 15. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: Medical. Written. Hartford, July 8-9. Endorsement. Hartford, July 22. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Homeopathic. Derby, July 15-16. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: July 8-10. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

FLORIDA: Jacksonville, June 23-24. Sec., Dr. William M. Rowlett, Box 786, Tampa.

HAWAII: Honolulu, July 14-17. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDAHO: Boise, Oct. 7. Dir., Bureau of Occupational License, Mr. Walter Curtis, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, June 24-26. Supt. of Registration, Mr. Lucien A. File, Department of Registration and Education, Springfield.

INDIANA: Indianapolis, June 17-19. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, Citizens Trust Bldg., Fort Wayne.

KANSAS: Kansas City, June 17-18. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

LOUISIANA: New Orleans, June 12-14. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

MAINE: Augusta, July 1-2. Sec., Board of Registration in Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Medical. Baltimore, June 17-20. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. Homeopathic. Baltimore, June 17-18. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, July 8-11. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Ann Arbor and Detroit, June 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: Minneapolis, June 17-19. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Jackson, June 25-26. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, Oct. 6-8. Sec., Dr. Otto G. Klein, First National Bank Bldg., Helena.

NEVADA: Reciprocity with oral examination, Aug. 4. Sec., Dr. Fred M. Anderson, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, June 17-18. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 13-14. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 23-26. Chief, Bureau of Professional Examinations, 315 Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 16-20. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, July 1-4. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: Practical, June 11 and 14. Written, June 12-13. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: Oklahoma City, June 11-12. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: Portland, July 24-26. Final date for filing application is July 9. Exec. Sec., Miss Lorraine M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 8-12. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. Marguerite G. Steiner, 358 Education Bldg., Harrisburg.

RHODE ISLAND: July 10. Acting Chief, Division of Examiners, Mr. E. Clyde Thomas, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 23-25. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, July 15-16. Dir., Medical Licensure, Dr. J. F. D. Cook, State Board of Health, Pierre.

TEXAS: Austin, June 16-18. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas.

VERMONT: Burlington, June 17-19. Sec., Dr. F. J. Lawless, Richford.

VIRGINIA: Richmond, June 17-20. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WASHINGTON: Seattle, July 21-23. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

WEST VIRGINIA: Wheeling, July 7-9. Sec., Public Health Council, Dr. C. F. McClintic, State Capitol, Charleston.

WISCONSIN: Milwaukee, June 24-27. Sec., Dr. H. W. Shutter, 425 E. Wisconsin Ave., Milwaukee.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Tucson, June 17. Sec., Mr. Franklin E. Roach, Science Hall, University of Arizona, Tucson.

CONNECTICUT: June 14. Address State Board of Healing Arts, 1945 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, Oct. 20-21. Sec., Dr. George C. Ruhland, 203 District Bldg., Washington.

IOWA: Des Moines, July 8. Dir., Division of Licensure and Registration, State Department of Health, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

OREGON: Corvallis, July 12. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Aug. 20. Acting Chief, Division of Examiners, Mr. E. Clyde Thomas, 366 State Office Bldg., Providence.

SOUTH DAKOTA: June. Sec., Dr. G. M. Evans, Yankton.

WASHINGTON: Seattle, July 17-18. Sec., Department of Licenses, Mr. Nelson N. Vaughan, Olympia.

Colorado January Report

The Colorado State Board of Medical Examiners reports the written examination for medical licensure held at Denver, Jan. 8-10, 1941. The examination covered 8 subjects and included 68 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. Nine physicians were licensed to practice medicine by endorsement of a state license and 1 physician so licensed by endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Colorado School of Medicine	(1939)	85
Northwestern University Medical School	(1940)	89.5
State University of Iowa College of Medicine	(1940)	86
School	LICENSED BY ENDORSEMENT	Year Endorsement of Grad.	
College of Medical Evangelists	(1939)	N. B. M. Ex.
University of Michigan Medical School	(1938)	Florida
University of Minnesota Medical School	(1939)	Minnesota
Washington University School of Medicine	(1934)	Missouri
University of Nebraska College of Medicine	(1930)	Nebraska
Univ. of Rochester School of Medicine and Dentistry	(1935)	New York
Ohio State University College of Medicine	(1930)	Minnesota
University of Oklahoma School of Medicine	(1938)	Oklahoma
University of Oregon Medical School	(1936)	Minnesota
University of Tennessee College of Medicine	(1937)	Tennessee

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Evidence: Osteopath as Expert Witness in Malpractice Suit Against Clinic of Nonsectarian Physicians.—The plaintiff, a woman aged 75, broke "her left leg below the knee" Nov. 13, 1937. She was taken to the defendant hospital and clinic where roentgenograms were taken, the fracture was reduced and she was attended by nonsectarian physicians. She was discharged from the hospital Jan. 29, 1938. Her leg, however, was "not straight" and was swollen and it was necessary for her to use a cane. She subsequently sued the hospital and clinic for malpractice. She offered as a witness an osteopath who, after viewing roentgenograms taken of the leg at the hospital while the leg was still in a cast, was asked whether or not the roentgenograms showed "a proper setting of that leg." The court refused to permit the osteopath to answer, in effect refusing to permit the witness, because he was an osteopath, to qualify as an expert witness in the case, relying apparently on the theory that when a physician is sued for malpractice his treatment of the patient can be tested only by the rules and principles of the school of healing to which he belongs. To qualify the witness to testify, counsel for the patient then offered to "prove that the method of reduction of fractures by an osteopathic physician and surgeon and by a medical physician and surgeon are the same; that they use the same textbooks and the methods of reduction as taught in the two schools are the same." The trial court refused this offer of proof and later directed a verdict in favor of the defendant hospital and clinic. The plaintiff appealed to the Supreme Court of Missouri, division 1, assigning error in the refusal of the trial court to receive evidence that would have qualified the defendant to testify as to the negligence of the defendant hospital and clinic, which in turn might have constituted sufficient evidence to require the case to be submitted to the jury.

In an action for malpractice, said the Supreme Court, a physician or surgeon is entitled to have his treatment of his patient tested by the rules and principles of the school of medicine to which he belongs, and if he performs the treatment with ordinary skill and care in accordance with his system he is not answerable for bad results. However, this does not mean that no testimony of a practitioner of one school is competent in a malpractice case against a practitioner of another school. A practitioner of the healing art is "competent to express an opinion as to matters of diagnosis and to testify to any scientific fact that is, or ought to be, known to every physician and surgeon of every school or system." As was said by the Supreme Court of Washington in *Swanson v. Hood*, 99 Wash. 506, 170 P. 135:

The rule is not that a physician of another school is not competent to testify, but that a defendant's treatment is to be tested by the general doctrine of his own school, which is a very different thing; in other words, the standard of exclusion of evidence is not the school of the witness, but the premises of his testimony. If the premises from which he testifies, that is to say, the criterion by which he measures defendant's treatment, are those of defendant's own school, the witness is not disqualified merely because he himself belongs to another school. . . . When it once appeared that the osteopathic physician was basing his testimony on the tenet of appellant's own school, his testimony was admissible; its weight was for the jury.

It is apparent, continued the Supreme Court, that in this case the trial judge took the position that the osteopath could not qualify as an expert in the case solely because he was not a graduate of any medical school. In so ruling, the trial court disregarded the ruling of this court in *Grainger v. Still*, 187 Mo. 197, 85 S. W. 1114, 70 L. R. A. 49, that, if "it should appear that both the schools to which the witnesses and the defendant belonged employed the same treatment" to the condition under consideration, testimony as to propriety of treatment would be competent. As to how similarity of methods might be shown, it was said in *Swanson v. Hood*, supra, that

such testimony "is admissible, though it be based on the study of books rather than on his own experience." Here the patient sought to show that the methods of reduction of fractures as taught in the two schools are the same, "not only from [the osteopath's] study of books, but also from experience gained over a long period of time he had practiced with M.D.'s in this and similar fractures," and, furthermore, "that the same textbooks and authorities are used by the followers of both schools" as to treatment of fractures. Whether or not the witness did know what he purported to know was of course another matter, which could go to the weight of his testimony only if he made a prima facie showing of qualifications. He was not even allowed to show what his qualifications were by stating what his experience and study had been. Neither was he permitted to testify as to what was shown by the roentgenograms taken by the defendant when the patient was in the hospital with her leg in a cast; and the basis of objections and rulings did not go to his qualifications to understand and interpret roentgenograms. It was pointed out to the Supreme Court that the Missouri statutes require a doctor of medicine to study and pass examinations in anatomy, physiology and surgery and also impose these requirements on an applicant for a license to practice osteopathy. Other similar studies are required of both physicians and osteopaths. Certainly, said the Supreme Court, reduction of fractures is a very different matter from the treatment of disease by medicine. It does not seem unreasonable that the study and methods of the two schools of practice, that is nonsectarian medicine and osteopathy, would be the same in many respects as to treatment of fractures. Even a layman has some idea about what must be done. We hold, concluded the Supreme Court, therefore, that it was erroneous to refuse to permit the osteopath to show his qualifications and to show the extent of similarity of study and methods of the two schools.

Accordingly, the judgment in favor of the defendant was reversed and the cause was remanded to the lower court for trial.—*Mann v. Grim-Smith Hospital and Clinic*, 147 S. W. (2d) 606 (Mo., 1941).

Insanity: Permanent Compulsory Detention on Certificate of Two Physicians Illegal.—A Vermont statute (Public Laws, sec. 4034) provides that no one shall be admitted to or detained in a hospital for the insane except on the certificate of two licensed physicians that the person is insane. By another statute (sec. 4038) a person so certified to as insane, or any next friend or relative, may appeal from the "decision" of the physicians so certifying to the appropriate probate court, which is then to try the issue of insanity with the aid of a jury.

Helen B. Cornell was admitted to Brattleboro Retreat, April 23, 1936, on the certificate of two physicians that she was insane and was detained there until the conclusion of the proceedings here abstracted. In November 1940 she attempted to appeal to the appropriate probate court, which dismissed her petition. The action of the probate court was affirmed by the Supreme Court of Vermont because of the delay of more than four years in applying for an appeal. In *re Helen B. Cornell*, 18 A. (2d) 151. A writ of habeas corpus was then filed on her behalf with the Supreme Court of Vermont, alleging that she was detained in the retreat referred to against her will and that her detention was violative of rights guaranteed to her by the state and federal constitutions.

At common law, said the Supreme Court, a person alleged to be insane, preliminary to the institution of judicial proceedings for the consideration of his mental condition, may be temporarily restrained without legal process if his being at large would be dangerous to himself or others, and such a restraint does not violate any constitutional provision. When, however, the confinement is permanent in nature, in order to be lawful it must be in pursuance to the judgment of a court of competent jurisdiction after such a person has had sufficient notice and adequate opportunity to defend. Notice and opportunity to defend are required by (1) article 10 of the state constitution, which reads in part as follows:

Nor can any person be justly deprived of his liberty, except by the laws of the land, or the judgment of his peers,

and (2) by that portion of the Fourteenth Amendment to the Federal Constitution providing that no state shall "deprive any person of life, liberty, or property, without due process of law." The court concluded that a permanent detention under the circumstances here present was violative of the constitutional rights referred to.

To execute such a certificate as is here in question, said the court, any two qualified physicians may be selected by those interested in having the person confined, regardless of other actuating motives. The physicians are neither designated, appointed nor commissioned by any court or public authority to act in that capacity. The physicians must examine the person within five days prior to executing the certificate under oath. The examination may be made without notice to, or knowledge by, the supposed insane person, and solely on such examination their certificate may be based. The physicians are not obliged to hear any other evidence, even though offered by the person examined or in his behalf to show his sanity, and if they do hear evidence so offered it is as a mere matter of favor on their part. A certificate of physicians executed under such circumstances cannot have the force of judicial determination as to the state of a person's mind. The certificate is not by law returnable to any court, public officer or public office. It is not a warrant, nor a binding order on any one, to commit to an asylum, or to restrain, the person certified to be insane. It is only the written opinion under oath of the physicians that the person is insane and is a proper subject for treatment and custody in some asylum. Having concluded that the confinement of Helen B. Cornell if permanent was illegal, the court also concluded that the detention was not temporary but permanent in character and ordered her discharge from custody.—*In re Cornell*, 18 A. (2d) 304 (Vt., 1941).

Taxes: Salary of Physician Employed by State Hospital Not Exempt from Federal Income Tax.—The plaintiff served, on a part time basis, as the senior gynecologist in the Pondville State Cancer Hospital. He was paid an annual salary. While he was answerable to the chief of staff and the superintendent of the hospital for keeping the gynecologic services of the hospital up to a proper standard, neither of these officers exerted any control over him as to the method and type of treatment that was to be accorded to any patient. Having paid a federal income tax, under protest, on his salary for the year 1932, the plaintiff filed suit in the United States district court, D. Massachusetts, to recover the amount paid.

The plaintiff first contended that his income from the hospital was not taxable because the hospital was an agency or instrumentality of the state engaged in an essential governmental function. In the opinion of the court, however, the case of *Cook v. United States*, 26 F. Supp. 253, was determinative of this question. In that case it was held that the Worcester City Hospital was not engaged in an essential governmental function and that a radiologist employed part time therein was not immune from federal income taxes. Neither could the court agree with the plaintiff's contention that his salary was exempt from taxation because of the provisions of the Public Salary Tax Act of 1939. That act subjected to federal income taxes the salaries of state officers and employees but exempted from taxation salaries earned prior to 1939. In the opinion of the court the plaintiff was not an officer or employee of the state but was an independent contractor, and hence did not come within the terms of the Public Salary Tax Act. The court therefore denied the relief sought and the plaintiff appealed to the United States circuit court of appeals, first circuit.

In the oral argument before the circuit court of appeals, the government waived the question as to whether or not the Pondville Hospital was an agency or instrumentality of the state. The only question on appeal, therefore, was whether the plaintiff during the year 1932 was an employee of an agency or instrumentality of the Commonwealth of Massachusetts so that his compensation for services was exempt from taxation under the provisions of the Public Salary Tax Act of 1939. The circuit court of appeals said that the basic distinction between employees who are immune from taxation and independent contractors who are not immune is the degree of control exercised

over their services, along with the hours of work, freedom to engage in other professional activity, continuity of employment and the like. And the question of control is a matter to be settled by the circumstances of each particular case. In those cases in which it has been held that professional men were employees, the court pointed out, it was found that the state or local agency had first call on their services and could make use of their entire time to the exclusion of private pursuits. On the other hand, where professional men have been held to be independent contractors and subject to taxation, stress has been laid on the ability of the taxpayer to carry on private work and the fact that he was simply required to reach a particular result with little or no control over the method of attainment.

The fact that the plaintiff in this case, the court observed, may have been included in the definition of "employee" in the statutory authorizations under which he was hired and pursuant to which his salary was regulated was not controlling. Neither was it vital that the plaintiff, in 1932, was paid on a salary basis rather than on the former fee basis, since the duties performed were the same and the change in the method of compensation was made solely for reasons of economy and not in order to change the relationship between the parties. The method of measuring compensation, in the opinion of the court, was of little significance. The plaintiff, continued the court, was not subject to sufficient control to be considered an employee. He was in complete charge of the gynecologic service at the hospital and no one told him how to treat the patients under his care. The hospital was interested only in the satisfactory coverage of the service. Furthermore, the plaintiff gave up only a small portion of his time to the hospital and was under no obligation to give the hospital patients preference over his private patients. The income he derived from the hospital was but a small proportion of his total annual income. He occupied the same position he would occupy if a single patient paid him a yearly sum to examine him weekly and for the sake of convenience requested a particular form of report and fixed hour for the examination, which the physician might vary by arrangement, and the court found difficulty in considering such a physician as an employee of his patient. Furthermore, observed the court, it is well established that there is no such relation of employer-employee between a hospital and its visiting surgeons sufficient to support an action against the hospital to require it to respond in damages for any negligent treatment of a patient by one of its physicians.

The court concluded, therefore, that the tax in question was legally assessed and collected and that a refund thereof was properly denied. The judgment of the district court against the plaintiff was affirmed.—*Meigs v. United States*, 30 F. Supp. 68 (1939); 115 F. (2d) 13 (1940).

Society Proceedings

COMING MEETINGS

- American Association for Thoracic Surgery, Toronto, Canada, June 9-11. Dr. Richard H. Meade Jr., 2116 Pine St., Philadelphia, Secretary.

- Utah State Medical Association, Salt Lake City, June 12-14. Dr. D. G. Edmunds, 610 McIntyre Bldg., Salt Lake City, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

11:83-174 (Feb.) 1941

Heparin as Anticoagulant in Sedimentation Tests: Comparative Study. S. W. Sappington and L. M. Gillis, Philadelphia.—p. 83.

*Transfusion Reactions: Experiences with More Than 3,000 Blood Transfusions. A. S. Wiener, B. H. Oremland, M. A. Hyman and A. A. Samwick, Brooklyn.—p. 102.

Stabilization of High Vacuum-Dried Guinea Pig Complement Before Drying and After Restoration with Water. F. Boerner, E. W. Flodorf and Marguerite Lukens, Philadelphia.—p. 122.

Syphilitic Aneurysm of Heart: Case Report with Review of Literature. C. G. Aronstein and L. Neuman, Washington, D. C.—p. 128.

Seminoma and Teratoma in Same Testis: Report of Case. J. R. McDonald and A. C. Broders, Rochester, Minn.—p. 138.

More Sensitive Biotitration of Optimum Erythrocyte Maturation in Human Anemic States. B. C. Houghton and C. A. Doan, Columbus, Ohio.—p. 144.

Anatomic Diagnosis of Acute Appendicitis. O. Saphir, Chicago.—p. 163.

Transfusion Reactions.—Wiener and his associates discuss the reactions occurring among 3,000 transfusions. All blood is typed before transfusing by testing the serum and the cells and cross matching the blood of the donor and the patient. Because of the human factor, even with these precautions there were 2 patients who were given blood of the improper group. In 1 a definite, though not serious, hemolytic reaction occurred. The transfused blood was quickly eliminated from the body of the 2 patients and this was followed by the appearance of immune isoantibodies of high titer in the patient's serum. In the patient of group AB, subgroup A₁B, who had received two transfusions of group O blood, anti-O agglutinins were observed in the serum. This suggests that the production of immune anti-O isoantibodies should probably be considered in repeated transfusions of blood from universal donors. Other complications occasionally encountered were thrombosis of the vein at the site of injection, at times associated with phlebitis, and suppuration of the wound in cases in which an incision was necessary. These complications were infrequent and never retarded convalescence. The idea that the rapid introduction of blood is dangerous for patients with endocarditis or thrombophlebitis seems to be supported by the sudden death of a patient with subacute bacterial endocarditis during a transfusion by a syringe-valve method. This was the only fatality that must be attributed directly to the transfusion. While the majority of chills following transfusion are caused by nonspecific agents (unclean apparatus) and do not nullify the hemoglobin rise, they may be part of a more serious syndrome. The first step in differentiating nonspecific chills from those of incompatibility of the donor's blood is to repeat the grouping and cross matching tests on samples of blood obtained before transfusion and also on fresh samples to determine whether there has been an error in grouping. The patient's sample taken after transfusion should also be examined for hemoglobinemia and its icterus index. The urine should be examined. When the patient and donor are of the same blood group, tests for M-N should be made. If the M-N types of patient and donor are different, tests on the patient's blood with anti-M and anti-N serums will demonstrate whether the donor's blood is still present in the patient's circulation. If it is present, a hemolytic reaction is excluded. If the M-N types are the same, hemoglobin determinations must be depended on. From five to ten days after transfusion the patient's serum should be matched against the donor's cells to detect any immune isoantibodies which may have formed.

Heart Disease Among Students.—Cole states that among the 28,139 students admitted to the University of Wisconsin between 1931 and 1939 who were given complete physical examinations there were 289 with heart disease. The sex ratio was 1.7 females to 1 male. This is a higher proportion of females than is commonly observed. The mitral valve was most frequently involved and it was clinically diseased in 91 per cent of the cases, the next most frequent site was the aortic valve in 15.5 per cent and there were only 2 cases of involvement of the pulmonic valve. Cardiac enlargement was shown to be present in 31.8 per cent of the patients, and 15.9 per cent had elevated blood pressures. Pericardial changes were observed in 14 cases. Disorders of rhythm were present on the electrocardiograms in 11 cases. More studies of this type, in view of the similarity of circumstances and conditions surrounding college students, would give an additional impetus to furthering preventive medical practice.

Sodium Sulfapyridine for Pneumococcal Infections.

According to Winters and his collaborators, the advantages of the intravenous administration of sodium sulfapyridine outweigh the disadvantages in the treatment of pneumococcal infections. The material for their study consists of 80 patients with pneumonia who were severely ill at the time of admission or who failed to respond to oral sulfapyridine. The potential toxicity of the drug was considered, but it was decided that treatment of the infection was more important and urgent than its possible toxic effect. Sodium sulfapyridine intravenously should not replace its oral use, but its parenteral use is definitely desirable for patients who are unable to have serum or to retain the drug orally or for those who are unable to cooperate because of coma or delirium. All but 1 of 13 patients who failed to respond to oral sulfapyridine and 4 patients who had a relapse made a prompt favorable response after sodium sulfapyridine was given intravenously. The high mortality (22 deaths) is readily explained by the fact that only those cases with a grave prognosis were selected for treatment with intravenous sodium sulfapyridine. Accidents may follow the intravenous use of sodium sulfapyridine, but these may be avoided by careful preparation and administration of the solution. The authors encountered no severe toxic reactions among their one hundred and fifteen intravenous injections. The response to treatment was more immediate with intravenous sodium sulfapyridine than with oral sulfapyridine. Repeated at intervals of twelve hours a dose of 0.06 Gm. per kilogram of weight maintains a level of from 6 to 15 mg. per hundred cubic centimeters. The fear of reactions following its intravenous administration seems unwarranted and should not limit its more general application.

Fluoroscopy in Detecting Pulmonary Tuberculosis.—Israel and Hetherington point out that the duplicate fluoroscopic and roentgen examinations given 1,021 patients who had a history of respiratory symptoms or of exposure to tuberculosis indicate that fluoroscopy provides an accurate method for the detection of pulmonary tuberculosis. In 329 patients abnormalities appeared definite or probable and in the remaining 692 patients in whom no definite abnormality was reported on fluoroscopic examination only 4 had clinically significant tuberculous lesions. Fluoroscopy failed to detect the small apical infiltrations that would be merely observed or disregarded by the clinician in 18 instances. These were not necessarily the obsolete minimal apical lesions which represent, as Hedvall has shown, the earliest roentgen evidence of pulmonary tuberculosis. The lesions described by Hedvall are demonstrable only after the most careful roentgen study and are at present overlooked by most roentgenologists and disregarded by most clinicians. Fluoroscopic examination will detect infiltrations so hidden by superimposed bony structures that they are not detected on single roentgenograms. Infiltrations have been found on fluoroscopic examination of 2 students in whose films, taken at another institution, no certain abnormality could be distinguished. Tuberculous infiltrations can be detected in children with even greater accuracy. Tuberculous tracheobronchial lymph node enlargement, definite on roentgen examination, was detected in all but 2 instances by fluoroscopy. When lymph node enlargement was definite or probable on one method of examination it appeared the same on the other. It is questionable whether roentgen or fluoroscopic examination is the more authoritative in the diagnosis of tuberculous lymph node enlargement and calcified primary lesions. In a number of instances calcification appeared definite on fluoroscopy, while flat roentgenograms showed no abnormality that would warrant such a diagnosis. An even larger proportion of cases in which a calcified primary lesion was diagnosed from flat roentgenograms was considered negative on fluoroscopy.

Causes of Menometrorrhagia.—Henriksen lists the clinicopathologic data in 1,500 cases of menometrorrhagia. The series is divided into two groups: Group A includes the 729 cases in which either the specimen removed at operation was obtained or the major factor was visualized or outlined by examination, and group B includes the 771 cases in which the diagnosis was made with the aid of examining endometrial and/or cervical tissue. The major causes of the abnormal bleeding among the first group were unknown in 197, benign cervical lesions in 148, uterine myomas in 108, ovarian in 76, pelvic inflammation in 76, malignant cervical changes in 57, tubal gestation in 27, senile vaginitis in 17, internal endometriosis in 16, urethral in 4 and rectal in 3. In group B the causes were follicular in 187, possibly functional in 124, pubic in 103, endometrial polyps in 102, incomplete menstruation in 82, endometrial hypertrophy in 70, postabortal in 53, inter-

menstrual bleeding in 33, general in 8, postirradiational in 5, tuberculous in 2 and abnormal gestational in 2. All the patients were between 20 and 40 years of age; thus the endocrinopathies of early adolescence and the menopause were not operative. A summary of the cases reveals no typical set of symptoms peculiar to specific pathologic changes of either the uterus or the ovaries. The patient with the minimum of demonstrable changes may bleed more profusely than the one with widespread pathologic pelvic changes. In spite of anatomic lesions, other factors must be considered as probably precipitating the abnormal bleeding. Not only must the problem be approached from an endocrine angle, but the clinicopathologic aspects must not be forgotten or discarded because of the waves of therapeutic and investigative enthusiasm. The misinterpretation of the endometrial patterns and the misapplication of terminology have done much to complicate the present status of investigative and therapeutic work in menstrual aberrations.

Deep Cauterization for Preventing Cervical Cancer.

Cashman states that control and prevention of cancer of the cervix do not lie in the method of treatment but in the early diagnosis and adequate treatment of the preexisting lesion, the chronic cervicitis or, even better, in the prevention of cervicitis by proper treatment of the cervix after delivery. The cervix has been cauterized in the material to be reported routinely, since 1914, in all operations for chronic tubal infection, in all subtotal hysterectomies and in all cases of cervical leukorrhea sufficient to warrant radical treatment. The infected cervix was cleaned up in any case in which operation was necessary for other conditions. Deep cauterization has been gradually adopted by gynecologic and obstetric staffs of the University of Pittsburgh Hospitals and there are now (over twenty-five years) 10,000 cases which have been followed up to determine the incidence of cancer in the cervixes so treated. Data were secured concerning 3,143 patients, and 1,341 of them returned for examination. The interval between cauterization and follow-up examination was from one to twenty-four years. Among the 10,000 patients 2 were known to have cancer of the cervix before the follow-up. In the 31.4 per cent follow-up, or 3,143 patients, no additional cases of cancer of the cervix were found. To determine the true prophylactic value of deep cauterization in this series the incidence of cancer among 10,000 gynecologic patients who have had no treatment of the cervix would be necessary. No such series is available, but certain estimates can be made from isolated surveys and published statistics. From this study it appears that the true incidence would probably lie between 19 cancers for 10,000 women in general and 182 for 10,000 gynecologic cases. According to Levin, who has applied accurate and scientific statistical methods to the author's data, the number of patients followed and the average duration of the follow-up were too small to constitute a fair test of the value of cauterization of the cervix in preventing subsequent carcinoma, and the facts obtained in this survey do not indicate that cauterization has any prophylactic value. In view of the importance of settling this question it is to be hoped that follow-up of these patients will continue.

Endometrium in Tuberculous Peritonitis and in Sterility.

Jensen and McDonald studied the pathologic changes in the endometria of 75 uteri removed in the course of surgical procedures; 25 of the uteri were removed surgically from women who had borne children and were not suspected of having tuberculosis before operation, 25 from women who had never borne children but were married and desired to have children, and 25 from women who had tuberculosis of the peritoneum verified by microscopic examination. In the first group tuberculosis of the uterus was encountered in 2, or 8 per cent, in the second group the incidence was 4 per cent and in the third group it was 60 per cent. The authors believe that endocervical tuberculosis was found more frequently than has been described previously. It seems likely that if more extensive microscopic study was to be made of the endometrium in routine curettage and hysterectomy the incidence of uterine tuberculosis would be found to be much higher.

Tuberculosis in Students.—According to Myers, the Tuberculosis Committee of the American Student Health Association reported that 25.5 per cent of 82,774 students examined during the 1938-1939 term reacted to tuberculin. If every test was read correctly, each of these students possessed tuberculous

lesions. Therefore approximately 25 per cent (with variations in different places) of students who enter as freshmen already have the disease in some form as manifested by the tuberculin reaction. They were infected before they entered college; the majority of them are noncontagious at the time of entrance and admission should not be refused. Nevertheless they have tuberculous lesions of at least the primary complex, and an occasional case of clinical tuberculosis should be expected while they are in school. The only solution of the problem is protection against infection throughout the precollege age. Already this is being done with such success that there is an appreciable decrease of tuberculin reactors among entering students. As accurate methods of screening out contagious cases are available, students need not contract tuberculosis while in college. If students are kept under sufficiently close observation, only rarely will a student enter with a contagious stage of the disease or will a case develop on the campus and dissemination to other students occur. No member of the personnel of an institution who has contagious tuberculosis should be permitted direct or indirect contact with the students. Immunization and vaccination studies against tuberculosis have resulted only in controversy; therefore the weapons to employ are those found of universal value. Definitely established facts, when properly applied, are sufficient to control the disease on any campus.

Constitution and Diet in Tuberculosis.—Heise declares that the evidence that resistance or susceptibility to tuberculosis is largely an inherited quality has been obtained from (1) the incidence of the disease and its fatality in the general population during successive years, (2) the effect of tuberculosis on racial stocks, (3) its effect on masses of people recently in intimate contact with it, (4) its incidence and fatality rate in family trees or stocks over long periods of time, (5) difference in incidence between fraternal and identical twins living in the same environment and (6) experimental work on animals. The inherited resistance can be strengthened or weakened by the food eaten. Evidence of this is had from studies of the effect of food shortages on populations during war and other economic disasters. Also that the resistance can be enhanced by feeding larger than usual quantities of qualitative or protective foods has been shown experimentally. The isolation of a patient with open tuberculosis has reduced the chances of infecting others and perhaps lessened the infecting dose and possibly repeated infections. Natural laws have acted to weed out the susceptible in successive generations. Better dietary habits have enhanced inborn resistance to all diseases, including tuberculosis. The inherited constitution and the better understanding of nutrition have played their part in reducing the tuberculosis mortality rate.

Nipple Discharge.—Hinchey discusses the frequency, type and etiology of discharge from the nipple as seen in 67 cases. The series excludes cases of discharge from inverted nipples or from ulcerated nipples found in cases of Paget's disease. Carcinoma, chronic cystic mastitis and papilloma were the three lesions responsible for about three fourths of the cases. The papilloma is a precancerous condition, and chronic cystic mastitis, with epithelial hyperplasia, is also to be regarded as precancerous. Twenty-four of the women had cancer; in 12

the discharge was nonsanguineous. In 11 women the discharge was the first warning of disease of the breast, and 4 women had no mammary mass at the first examination. Contrary to common experience, chronic cystic mastitis was encountered more than twice as often as papilloma. The discharging breast in which no mass is palpable must be suspected of harboring not only the precancerous conditions of a papilloma or chronic cystic mastitis with epithelial hyperplasia but even actual cancer. Treatment consists in local surgical excision or mastectomy. Irradiation has not proved of value. A few cases require merely observation, but the surgeon should make this group as small as possible by considering all the possible surgical indications. Thus will important cancer-preventive surgery be performed and occasionally an early, impalpable cancer be discovered. There are five groups of patients with nipple discharge and no tumor in which surgery, in the author's opinion, is definitely indicated: (1) nipple discharge with positive transillumination, (2) nipple discharge with positive pressure test, (3) nipple discharge with localized nodularity in the breast, (4) nipple bleeding after the menopause and (5) continued nipple bleeding of undetermined origin. The presence of blood in the discharge is significant, but its absence cannot rule out a dangerous lesion. Diagnosis is established by the finding of a continuous milky or a greenish yellow discharge which respectively indicate galactorrhea or duct stasis.

Malignant Melanoma.—De Chohnoky believes that lack of information concerning the extremely malignant lesions (melanomas) that may arise from moles following trauma or chronic irritation is responsible for the patients' long delay in seeking treatment. The results obtained by surgery are encouraging, but improper treatment or irritation of pigmented lesions must be prevented. Collaboration between the public, practitioners and surgeons is desirable for eliminating those pigmented areas which may undergo malignant degeneration. Beauty parlors, chiropodists and the like need to be warned about the possible consequences of insufficient treatment of the dark pigmented moles. Darkly pigmented nevi which are subjected to irritation should be excised or coagulated. Chemical irritations, caustics and electric methods which do not destroy the entire lesion are to be avoided. Roentgen ray and radium therapy may destroy a local lesion, but authenticated cures following their use are rare; therefore it is not recommended for operable cases. Electrocoagulation followed by lymph node dissection may be desirable for destroying the local lesion. Radical surgery is the treatment of choice and should consist of wide local excision including surrounding subcutaneous fat tissue and underlying fascia, followed by regional lymph node dissection. Removal of the lymphatic vessels in the subcutaneous fat tissues around the lesion and between the lesion and the regional lymph nodes may be desirable in irritated lesions. Amputation of the fingers, toes and foot is advocated for anatomic reasons. This may improve the percentage of "five year arrests," which today occur in about one third of the cases. The author's statistics of 117 cases show five year arrests in 42.3 per cent and ten year arrests in 19.2 per cent of the cases. Untraced cases were reported as deaths.

Smoking and Thromboangiitis Obliterans.—According to Theis and Freeland, tobacco smoking was usually accompanied by a greater reduction in the oxygenation of the arterial blood in patients with thromboangiitis obliterans than in normal persons. The extent of the reduction seemed to be influenced by physiologic adjustments in the blood pressure, pulse rate and peripheral skin temperatures. Occasionally, when a decided increase in blood pressure and pulse rate followed smoking, the oxygen saturation of the arterial blood was found increased. The increase was greatest in patients recovered from thromboangiitis obliterans who, after a period of abstinence from smoking, had particularly low oxygen saturation. Failure of physiologic adjustments to compensate for the lowered oxygen tension in the tissues and internal organs may be an etiologic factor in thromboangiitis obliterans. The increased viscosity and other changes in the blood in thromboangiitis obliterans may be evidences of disturbed tissue metabolism. All subjects (16 normal persons, 19 patients with thromboangiitis and 10 with nonthromboangiitis obliterans) were stabilized in bed at room temperature for one hour with the body and extremities

covered by one sheet. Repeated observations were made on the blood pressure, pulse rate, respiratory rate and the cutaneous temperature of the toes and fingers. Arterial blood was obtained from the right radial artery and venous blood from the right antecubital vein. After stabilization and initial observations, successive cigarets were smoked at intervals of fifteen minutes and the foregoing studies made.

Moccasin Snake Venom for Herpes Simplex.—While treating a patient with blistering doses of ultraviolet rays for depressed acne scars, Fisher noticed that even mild erythema doses caused severe herpes simplex to recur in a certain area on the cheek, precluding further treatment. A moderately severe sunburn would also cause herpes to appear in the same area. The patient was given two doses of moccasin snake venom, 0.2 cc. of a 1:3,000 dilution, at intervals of one week. Three weeks after the second dose herpes no longer appeared even after exposure to strong erythematous and blistering doses of ultraviolet rays. The immunity has so far lasted for eighteen months. The treatment has been tried in 10 other cases of herpes of various parts of the face and in 4 cases of herpes progenitalis. Not enough time has elapsed to evaluate fully the importance of the method in these cases, but so far it has been effective. Most patients received two doses of snake venom, 0.2 cc. of a 1:3,000 dilution, subcutaneously one week apart. Within a half hour after the injection the site of the injection became moderately tender and swollen. The patients described the reaction as a sensation like that of being struck on the arm. The sensation disappeared in from three to four hours after the injection. In 3 patients, given more than two injections, swelling, redness and itching developed at the site of injection and subsided in from eight to ten hours. There were no general reactions. Moccasin snake venom may be effective in cases in which smallpox vaccination fails.

Nonpellagrous Eruptions Due to Vitamin B Deficiency.—Gross reports 13 instances of a cutaneous eruption not quite conforming with any well known dermatologic entity. The common feature in all of the patients was their response to parenteral liver therapy, which suggested that the eruptions were due to a deficiency of the vitamin B complex. Diagnosis of pellagra was not permissible, as the cutaneous manifestations were not typical of the disease, nor were they associated with mucous membrane lesions of the mouth, gastrointestinal disturbances or mental symptoms. The classification as nonpellagrous eruption due to deficiency of the vitamin B complex seemed justified. It is the author's impression that the condition in his cases in many ways follows the pattern of the cutaneous manifestations of well defined deficiency diseases (ariboflavinosis, pellagra, tropical avitaminosis and the Plummer-Vinson syndrome). The extensive and localized eruptions responded to treatment with liver extract. He suggests that the condition is a vitamin B complex deficiency and that the deficiency is due to low intake only in occasional instances. More commonly it is based on a constitutional predisposition

which may be identified with the so-called seborrheic diathesis. He makes no claim for a curative effect of liver therapy in the average case of seborrheic eczema, but further studies and a more rational therapy with synthetic products are necessary to clarify the role of vitamin therapy in this disease. Extensive monilial infections of the skin, vulval and anal eczema, kraurosis vulvae and arspenamine dermatitis have responded promptly to liver therapy. The relation of monilial infection to diabetes is reviewed from the newer knowledge of a vitamin B complex deficiency in persons with diabetes.

Fluid Replacement in Surgical States.—Maes and Davis consider the abnormal physiologic picture which follows loss of water, plasma, electrolytes and blood, the technic of fluid replacement and the present status of transfusion of ascitic fluid. Minor grades of dehydration uncomplicated by large losses of electrolytes or blood may be treated by giving water orally or rectally. Many dehydrated patients may require treatment with fluids intravenously. Electrolyte replacement in the presence of dehydrated states in which there is some loss of sodium, potassium and chloride ions may be deferred until hydration has been partially accomplished by means of isotonic dextrose solutions. As electrolytes diminish, the organism's ability to retain water decreases proportionately. The effects of a gradual loss are anorexia, nausea and a tendency toward muscular and mental fatigue and cramps. Some of the surgical causes which may result in loss of electrolytes are artificial openings in the intestinal tract (jejunostomy, ileostomy

or cecostomy) and prolonged drainage from a biliary fistula. Other causes are prolonged diarrhea, discharges from suppurating wounds, prolonged use of Wangensteen or Miller-Abbott gastrointestinal tubes, vomiting due to obstruction and excessive perspiration. Estimation of the level of plasma sodium chloride, which varies normally from 560 to 630 mg. per hundred cubic centimeters of blood, gives a direct clue to the extent of electrolyte loss. A study of the secondary effects of electrolyte loss provides an indirect method. Hypertonic solutions to replace electrolytes are contraindicated. An isotonic solution of 5 per cent dextrose with 0.9 per cent sodium chloride provides an excellent replacement fluid. The electrolyte loss plus the basic electrolyte requirement provides a clue to the amount of solution to be administered. If secondary dehydration has reached the stage of reduction of blood volume, it should be restored by blood transfusion or preferably by plasma or ascitic fluid transfusion. Thereafter, electrolyte solutions may be administered. When sodium is lost, with resultant acidosis and dehydration, relatively larger amounts of solutions of electrolytes may be administered. Desoxycorticosterone acetate will help to fix the sodium and, consequently, the water in the tissues. When the loss is confined mainly to the chloride ion with resulting alkalosis and dehydration, relatively smaller amounts of electrolyte solutions may be given. Fresh whole blood is the most efficacious fluid for replacing lost blood. If not always available, ideal substitutes, containing one or more of the elements of blood and possessing one or more of the biologic properties of blood, are preserved blood, hemoglobin in solution, blood plasma and serum and ascitic fluid. Even though ascitic fluid contains no hemoglobin, its use in acute loss of whole blood is rational as in such states there is usually enough hemoglobin remaining to carry on the respiratory functions of the blood. Only 3 Gm. of hemoglobin per hundred cubic centimeters of blood is necessary to maintain adequate oxygenation. The effects of loss of plasma or plasma-like fluid from the blood stream are dependent on the rate of loss and the nature of the fraction (aqueous or protein) lost. In acute loss of plasma with hemoconcentration and its sequelae, fluid should be replaced before the capillary walls have been irreversibly damaged by oxygen lack. Crystalloid and acacia solutions are contraindicated. The presence of hemoconcentration and increased viscosity of the blood suggests that solutions of normal human proteins without red blood cells might prove more effective than whole blood. Such solutions are plasma, serum and human ascitic fluid. If dehydration complicates the acute loss of plasma, crystalloid solutions may be given, but only after the plasma volume has been restored by protein-containing solutions. The most trustworthy criterion of the amount of plasma lost is the level of oxygen saturation of the blood. The therapeutic problem in chronic loss of plasma protein is correction of the disturbance of distribution of the body fluids resulting from lowering of the osmotic pressure of the blood. Therefore only protein-containing fluids (whole blood, plasma, serum and ascitic fluid) are indicated. Acacia solutions are contraindicated because of their deleterious action on protein regeneration. The danger of intravenous hypertonic and isotonic solutions of sodium chloride should be kept in mind when hypoproteinemia is present, as edema of the body tissues may be precipitated and such "salt" edemas are apt to resist treatment. Desoxycorticosterone acetate is contraindicated.

Postoperative Hypoprothrombinemia and Anesthesia.—Allen and Livingstone determined the prothrombin of 106 patients who underwent surgical procedures other than that of the biliary tract. Except in 1 case, no postoperative change was found in the prothrombin levels when ether, vinethene, nitrogen monoxide, ethylene-oxygen, avertin with amylene hydrate, nupercaine, spinal or local anesthesia was used. Loss of blood encountered at operation was determined on 11 patients and it was found that as much as a 785 cc. loss did not reduce the level of plasma prothrombin. In all but 2 of 13 patients with obstructive jaundice and 2 patients with bile fistulas who received preoperative vitamin K therapy for correction of prothrombin deficiency a sharp postoperative drop in prothrombin occurred despite the correction. The authors suggest that storage of vitamin K or prothrombin probably occurs within the body and that the failure to replenish this store in patients with obstructive jaundice or biliary fistula probably accounts for their postoperative hypoprothrombinemia.

Hepatic Glycogen Reserves in Diabetes Mellitus.—Mirsky and his associates developed a procedure whereby by the administration of phlorhizin it may become possible to gage the capacity of the human liver to maintain a normal concentration of glycogen. The renal threshold for sugar is lowered by the phlorhizin, and a sudden and rapid drain of sugar from the blood stream occurs. This results in a compensatory increase of hepatic glycogenolysis in an attempt of the liver to maintain the blood sugar level, thereby depleting its glycogen reserves. The loss of sugar via the kidneys can be measured in the urine. As long as the blood sugar level remains unchanged, the excreted dextrose must represent dextrose secreted by the liver, liver glycogen. However, when the level of the blood sugar decreases, the dextrose excreted in the urine represents not only dextrose which has been secreted by the liver but also some free sugar which was originally present in the blood and other body fluids. By appropriate calculations the sugar which must have originated in the liver can be estimated. If acetonemia occurs concomitantly with the hypoglycemia, it becomes evident that the liver has had only minimal amounts of glycogen and that the sugar in the urine now takes origin from newly formed dextrose in the liver. If the liver of the diabetic patient cannot retain normal amounts of glycogen, phlorhizin with the consequent decrease in renal reabsorption of dextrose will lower the blood sugar level, while the blood of a normal subject will show no change after losing the same amount of sugar. The more severe the metabolic disturbance, the greater will be the loss of glycogen and hence the greater the rapidity with which a decrease in the blood sugar

level will occur. Therefore the case with which hypoglycemia and acetonemia develop in consequence of dextrose removal via the kidneys provides a means for gaging the glycogen "reserves" of the liver of diabetic patients. The procedure was carried out on 25 normal and 23 diabetic adults and 25 normal and 15 diabetic children. All were permitted to have their regular evening meal, and at 9 p. m. orange juice or cane sugar to furnish 2 Gm. of carbohydrate per kilogram of body weight was provided for storage as hepatic glycogen. The next morning no breakfast and no food during the test were permitted. The diabetic subjects did not receive their morning dose of insulin, and those receiving protamine zinc insulin were given regular insulin the day before the test. The test was begun at 7:30 a. m. and completed six hours later. Water was allowed as desired. A sample of blood was drawn at the beginning and again at the end of the test and was analyzed for its sugar content and for total acetone bodies. Immediately after the first sample of blood, 1 Gm. of phlorhizin dissolved in tenth normal sodium hydroxide was injected intravenously. The subject then emptied his bladder. Another gram of phlorhizin was administered intravenously at the end of three hours in order to maintain a constant glycosuria. The urine was collected during the six hours of the test, and the total amount of dextrose excreted determined. At the end of the test period the patient was permitted to eat so as to compensate for the loss of sugar from the body. The authors found that diabetic adults do not retain carbohydrate in their livers to the same degree as do normal adults and that the removal of relatively small amounts of sugar from their blood stream results in further deprivation of liver glycogen with a consequent hypoglycemia and ketosis. Children cannot retain carbohydrate to the same degree as do adults because of an apparent increased rate of glycogenolysis. This is true not only for diabetic children but also for normal children and accounts for their greater susceptibility to ketosis and coma.

Insulin-Quinine Mixtures in Diabetes.—Cutting and Robson state that 7 of 10 patients with mild and severe forms of diabetes reacted beneficially to variable doses of an insulin-quinine mixture by mouth. About half of the patients showed variable degrees of cinchonism. The results obtained are regarded by the authors as encouraging concerning future possibilities of discovering more efficient and less objectionable agents than quinine for promoting gastrointestinal absorption of insulin. Meanwhile, they do not recommend the general use of the insulin-quinine mixtures used by them.

Hypertension in Relation to Height.—Robinson states that on the basis of a gross anthropologic study of 2,552 men and 2,021 women blood pressure is shown to be affected by height. In a random group of mixed builds and weights short men and women showed higher mean and modal systolic and diastolic blood pressures than tall men and women. Short men and women showed a higher incidence of high pressures than tall men and women. When the build groups were separated and held constant, a marked difference in blood pressure was observed between tall and short persons and was reversed to the foregoing height relationship. The unequal distribution of lateral build in short and tall persons explains this discrepancy. The tall lateral or broad person was more susceptible to hypertension than the short lateral one. Tall lateral or broad men showed an actual to expected ratio of about two and one half times as many systolic and diastolic hypertensive subjects as short lateral men. Among the tall lateral women there was twice as much systolic and diastolic hypertension as among short lateral women. Tall lateral women showed less than one third the low systolic and diastolic pressures shown by short lateral women. Tall lateral men had a slightly smaller inci-

dence of low pressure than short lateral men. The actual to expected ratio revealed that among linear or thin men the tall men had only one half as many low systolic and diastolic pressures as the short men. The actual to expected ratio indicated no difference between short and tall linear or thin women of low and high pressures. Although the tall person carries a greater hazard of hypertension than any other individual, the larger number of lateral builds among short persons causes the bulk of the hypertensive population to fall among this group. Short individuals show a higher incidence of hypertension than tall ones in any weight group. The three influencing height factors in hypertension are (1) the difference in blood pressure between tall and short persons of specific builds, (2) that between tall and short persons when weight is constant and (3) that between short and tall persons in any group in which build and weight are naturally mixed.

Disturbances in Blood Following Exposure to Benzene.—Goldwater studied hematologic changes of 332 individuals who had been exposed to benzene (benzol) for at least six months and up to sixty months. This group of workers were employed in the rotogravure printing industry in New York City. The concentration of the benzene fumes to which they were exposed ranged from 11 to 1,060 parts per million. For comparison, similar studies were performed on workers in a nonhazardous industry. The abnormalities most frequently observed among the benzene workers were anemia, macrocytosis and thrombocytopenia. Leukopenia was present in only a small percentage of the men who had been exposed to benzene. Comparison of the benzene group with the controls indicated that exposure to benzene is likely to result in both relative and absolute lymphopenia. Neutropenia was relatively rare. Monocytosis, lymphocytosis, eosinophilia and basophilia were not found. Prolongation of the bleeding time was rare and did not parallel the reduction in thrombocytes. Prolongation of the coagulation time was also rare. Relatively high hemoglobin values were a common observation. This abnormality was associated with macrocytosis as well as with overloading of erythrocytes with pigment. The erythrocyte sedimentation rate was apparently not altered. Erythrocyte fragility did not seem to be significantly altered on exposure to benzene, but there seemed to be a slight elevation of the serum bilirubin.

Vitamin C Survey in Diabetes.—Owens and his co-workers determined the vitamin C levels of 125 diabetic patients and compared the results with those obtained from 50 control subjects taken at random from the general medical clinic. None of the control patients were on a therapeutic diet. The 125 diabetic patients consisted of 100 unselected "old" diabetic patients followed regularly in the clinic and 25 "new" patients with no previous treatment. The status of the 100 "old" diabetic patients was considerably better than that of the controls but still far below optimal levels; 63 per cent had fasting blood levels below 0.8 mg. of vitamin C and 35 per cent had levels below 0.4 mg. per hundred cubic centimeters of blood. The authors believe that if diet instruction had not been given the blood level would have been in the same low range as in the uninstructed group. The levels of 76 per cent of the "new" diabetic patients were below 0.8 mg. and of 48 per cent they were below 0.4 mg. per hundred cubic centimeters. Exceedingly low levels were found in 50 nondiabetic patients; 90 per cent were below the optimal level of 0.8 mg. and 68 per cent were under the generally accepted critical level of 0.4 mg. The economic status of the nondiabetic patients and the diabetic patients was similar; none could afford the services of a private physician or could pay for hospitalization. Left to select their own diet on a limited allowance, they chose cheap foods that happened to be low in vitamin C. In spite of the low vitamin C

levels, no cases of scurvy were found among the nondiabetic patients. It is seen that the vitamin C status of diabetic patients is improved by diet instruction, even if the food expenditure of the diabetic clinic of the Cincinnati General Hospital is as low as \$2.10 a week per person. An attempt is made to design all diets for diabetic patients so that they are adequate in protein, minerals and vitamins. Diet classes are held weekly to acquaint ambulatory diabetic patients with the benefits of raw fruits and vegetables, in the hope that when possible they will select such foods.

Prostigmine Methylsulfate for Deafness.—Alexander used prostigmine methylsulfate for 44 cases of chronic catarrhal otitis media with or without tinnitus. Sixteen patients showed good recovery in hearing, 13 stated that their hearing acuity was better (but the audiograms of these patients failed to reveal any improvement), 5 patients with tinnitus were relieved with no improvement in hearing and the remaining 10 showed no improvement. In cases of bilateral chronic catarrhal otitis media in which the hearing was only partly lost in one ear and almost completely lost in the other ear prostigmine methylsulfate produced improvement in the better ear only. Along with catheterization and massage the patients were given 1 cc. of 1:2,000 prostigmine methylsulfate twice a week. Two patients had a recurrence of tinnitus, 1 after a month and 1 after two months. These 2 patients are still under treatment and have shown a definite improvement. The drug changed the character of the tinnitus of the 5 patients with no hearing loss; after the first injection 3 patients were completely relieved and the tinnitus of 2 was lessened to such an extent that it was hardly noticed. These patients were given prostigmine twice a week and no other treatment. Five patients with facial neuralgia were immediately relieved with prostigmine alone, and so far only 1 has had a recurrence and he was again relieved by a single dose of prostigmine.

Anemia in College Women.—Through blood studies of 364 college women with complaints and symptoms of anemia, Pryor and Ferguson find that achromic anemia is just as frequent as secondary anemia among women of the college age level. There were 145 instances of hemoglobin below 70 per cent which, according to Greene, is low enough to be classified as chlorosis. However, erythrocyte counts were relatively high, resulting in low color indexes in only 11 of the cases. The lowest hemoglobin was 42 per cent with an erythrocyte count of 3,920,000, producing a color index of 0.53, and is consistent with the diagnosis of chlorosis. A diagnostic point consistent with the classification of chlorosis and chlorotic anemia is the remarkable response of these students to simple treatment with iron tonics. The symptoms and complaints of these girls are no doubt traceable to loss in oxygen-combining and oxygen-carrying properties of the erythrocyte. The degree of impairment of normal body functions is probably the direct result of interference with cell nutrition and function. Dysmenorrhea is occasionally caused by anemia, when the erythrocytes fail to carry sufficient oxygen. When anemia is severe or of long duration the myocardium may be involved, and dysmenorrhea then develops as a result of myocardial weakness. The authors did not observe this type of dysmenorrhea among the 364 college women, but it is possible that the palpitation, syncope, low blood pressure and dizziness complained of by these patients could be explained on this basis. More than half of the girls in the series who had chlorosis, chlorotic anemia or achromic anemia complained of dysmenorrhea in some form, menorrhagia, metrorrhagia or deficiency or irregularity of flow. Dysmenorrhea was the most frequent complaint (54 per cent). The high frequency of menstrual disturbances among girls with the achromic anemias is consistent with the known age incidence (from 14 to 25 years) of chlorosis and appears to bear a definite relation to the establishment of catamenia. Since this type of anemia appears during adolescence it is thought to represent an endocrine imbalance during the time of sexual development. A study of body proportion or body build shows that 91 of the 145 girls were of slender build with width-length indexes more than one standard deviation below the mean for their ages. Linear type girls mature sexually at a later age than the lateral type and they have lower blood pressures, poorer musculature, more fatigability and are more highly strung and nervous. This appears to make the linear type of girl particularly predisposed to the symptoms and complaints of achromic anemias. Certain constitutional inadequacies evidently play a part in the development of these anemias.

Management of Complicated Hyperthyroidism.—Cattell states that, up to September 1940, 19,500 operations for goiter were performed at the Lahey Clinic. Of these approximately one half were for exophthalmic goiter. An additional 20 per cent had hyperthyroidism associated with preexisting goiter. In approximately 12 per cent of all toxic cases hyperthyroidism was complicated by other conditions. In one series of 7,363 patients with hyperthyroidism 424, or 5.8 per cent, had auricular fibrillation. Approximately 10 per cent have auricular fibrillation postoperatively. The preoperative treatment of such patients is directed toward the relief of decompensation, and at the same time the routine preparation (rest, compound solution of iodine, sedatives and a high caloric diet) is continued. Patients with decompensation and those with established auricular fibrillation or flutter are digitalized preoperatively and a maintenance dose is continued during the postoperative period. If digitalization does not cause the edema to disappear, diuretics are used. From two to three weeks is required to prepare such patients for operation and many may require stage operations. Immediately after operation all thyrocardiac patients are placed in oxygen tents for a minimum of forty-eight hours or until normal rhythm is restored. When the diagnosis of hyperthyroidism and concomitant pulmonary tuberculosis is made the thyroid condition should be treated first. A preoperative hospitalization of three weeks with the usual thyroid measures is indicated. Subtotal thyroidectomy can usually be done in one stage unless the hyperthyroidism is so severe that grade operation is indicated. The usual treatment of the tuberculous patient suffices to give the best convalescent care in the postoperative thyroid case. Diabetes and hyperthyroidism occur in 1.5 per cent of toxic thyroid patients. Any patient with diabetes who has an enlarged thyroid should be considered as one having possible hyperthyroidism. If hyperthyroidism is reasonably apparent, operation is indicated. Stage operations may be necessary for many of these patients. Patients with hyperthyroidism and diabetes who have had a subtotal thyroidectomy show improvement in the diabetic condition. Hyperthyroidism aggravates the diabetic condition, while subtotal thyroidectomy results in increase of carbohydrate tolerance and a decreased demand for insulin. Jaundice is present in approximately 0.5 per cent of toxic thyroid patients. Its presence usually indicates a crisis or an impending crisis. If the jaundice is due to disease of the biliary tract, its treatment is delayed until the hyperthyroidism has been relieved. If pernicious anemia with cardiac decompensation is the complication, it should be treated first and the iodine administration continued. In less severe cases a partial remission of the hyperthyroidism by medical means should be attempted while active treatment of the anemia is continued. If myasthenia gravis is the complicating illness, prolonged treatment with ephedrine and aminoacetic acid is indicated before thyroidectomy is considered. If there is any postoperative evidence of respiratory obstruction, tracheotomy should be done at once. The added risk is justified as the hyperthyroidism tends to aggravate the muscular weakness. Cancer of the thyroid in hyperthyroidism is a coincidental finding. Approximately 8 per cent of patients with true exophthalmic goiter or primary hyperthyroidism have a discrete fetal thyroid adenoma. Such an adenoma unquestionably is the seat of the malignant change in the rare cases in which it is encountered. When such a condition is present and is localized, total hemithyroidectomy is performed, with a subtotal hemithyroid-

ectomy of the opposite side. In the more extensive cases as complete a thyroidectomy as is practicable is carried out. In hyperthyroidism complicated by pregnancy, operation (subtotal thyroidectomy) is advised and carried out up to and including the eighth month. In patients with mild, diffuse infection of the upper part of the respiratory tract, operation is delayed until the infection has subsided. Focal infection should not be treated before the hyperthyroidism is relieved. Other operations for complicating gynecologic disorders should be planned for from three to six months after subtotal thyroidectomy. Operations for cancer of the stomach and colon in typical hyperthyroid patients can be performed from ten to fourteen days after thyroidectomy.

Heparin in Thrombosis and Blood Vessel Surgery.—Murray and his associates have given a purified nontoxic preparation of heparin to about 700 patients in sufficient doses to raise the clotting time to two or three times the normal level. Except for a few months in 1939, when thermal reactions occurred in about 50 per cent of their patients, there have been no toxic effects. The patients experience no more effect than that of an ordinary intravenous saline solution. The chief disadvantage of its use is that it is necessary for the patient to be in bed to receive the continuous intravenous injection. Intermittent injections two or three times a day to make the effect of heparin last a few hours are impracticable because so much must be given that the clotting time is elevated to several hours, which, of course, is undesirable and might be dangerous. There are no contraindications to the use of heparin except for patients with active bleeding from an open vessel, when the prolonged clotting time will encourage bleeding. Its administration is specifically indicated if the operation has involved a direct attack on blood vessels or when suture, repair or grafting of a blood vessel is necessary. The author has used heparin with satisfactory results in the following types of cases: arterial suture, arteriovenous fistula, venous grafts, embolectomy, mesenteric thrombosis, thrombophlebitis, phlebothrombosis and pulmonary embolism. Many of the operations might be performed with successful results without heparin, but with its use success is assured and the results have been most satisfactory. In thrombophlebitis, phlebothrombosis and pulmonary embolism there is less residual edema of the legs when the patient has been treated with heparin than when treated by other methods. When pulmonary embolism has occurred and the patient has survived long enough for heparin to be administered intravenously there has been striking clinical improvement. In 44 patients in whom no further embolisms occurred, rapid clinical improvement ensued. In 2 other patients further small embolisms may have occurred. This was not proved and the 2 patients recovered.

Carcinogens and Hormones in Cancer Research.

Morton reviews recent developments in the field of the carcinogenic agents, including the hormones, chemical carcinogens and light effects. There is no evidence that a definite chemical structure is necessary for carcinogenic activity. The chemicals vary from simple acids and alkalis, metal salts, radioactive compounds and sugars to complicated dyes, hydrocarbons, estrogens and viruses (heavy proteins). The "maximal effective" or "limiting dosage" indicates the quantity of the carcinogenic agent to which tissues respond. The limiting dosage varies from species to species. There is an intrinsic hereditary factor for cancer susceptibility or resistance. This factor may not necessarily be genic but at times extrachromosomal as well.

Animals of pure strain make for better controlled observations. Sex, season and the vehicle solvent should be considered. The carcinogens may unmask the latent spontaneous potentialities of the strain. Certain chemical carcinogens seem to have selective action on certain tissues. Epithelial growths, sarcomas and visceral carcinomas can now be induced by chemical means. Different species have tendencies toward different types of tumors. Each species and strain has its own characteristic tumor rate, organ susceptibility and latent period. The carcinogenic chemicals have a toxic action; locally they damage the tissues, inhibit growth. The damaged tissues may release substances which modify the neighboring cells, cause some hemolysis, have a photodynamic action and undergo metabolic changes in the body. In attempting to detoxify these chemical agents the essential sulfur containing amino acids may be used up. Some carcinogens are changed in the liver and intestine, giving fluorescence spectrums different from the originals. General systemic effects in the blood, lymphoid apparatus, vascular system and kidneys follow their application. The process may be considered as physiologic aging. The hormones are natural potential carcinogens. Under normal circumstances their functions are physiologic regulation. In repeated forced action they may become potent carcinogens. Many hormones are synergistic with or antagonistic to other hormones. Accentuation of their normal action or removal of the organ responsible for them may cause hypertrophy or atrophy of certain organs. Cancers may be induced in the overdeveloped organs or prevented by the absence of the organ. The process of cancerization still remains a mystery in its final steps.

Treatment of Gynecologic Cancer.—Kamperman discusses, on the basis of five and ten year cures, the 845 gynecologic cancers treated at Harper Hospital from 1922 to 1935 inclusive. He considers the more salient points of routine clinical procedures that have led to present day treatment. Since 1933 patients with gynecologic cancer have been irradiated with from 500 to 600 kilovolts more or less routinely. An evaluation of this change on the five year results is possible for three years. The 845 gynecologic cancers represent 636 carcinomas of the cervix uteri, 77 carcinomas of the fundus uteri, 171 carcinomas of the ovary and 31 carcinomas of the external genitalia. In tabulating the five and ten year results, patients who died from causes other than cancer were assumed to have died from cancer and the 2 per cent of untraced cases were likewise included among the dead from cancer. Thus the survival curves represent the lowest possible figures. In the earlier cases of carcinoma of the cervix, panhysterectomy and the Wertheim operation were occasionally performed, in conjunction with which high voltage roentgen therapy was always administered. Because of the apparent favorable results obtained from radium in some advanced cases its use gradually replaced surgical operations even in early cases. For carcinoma of the uterine fundus the earlier cases were considered adequately treated when a wide panhysterectomy was performed. Later both surgery and radiation were employed. During the course of time all surgical procedures, because of the addition of irradiation, were reduced to more conservative interventions. The irradiation technic consisted in the combination of intracavitary radium and external roentgen therapy whenever possible. From 1922 to 1928 the radium dose varied from 1,200 to 2,400 for a single to from 3,600 to 5,000 milligram hours for a total application. Since 1928 it has consisted of from 3,600 to 5,000 for a single to from 7,200 to 10,000 milligram hours for a total application. Apart from minor details from 1922 to 1932 the so-called high voltage roentgen therapy with 200 kilovolts (1 mm. of copper filter) was used, and since 1933 supervoltage roentgen therapy with from 500 to 600 kilovolts (7 millimeters of copper filter) has been substituted for most gynecologic cancers. For carcinoma of the cervix uteri the five and ten year survivals between 1922 and 1928 averaged 16 and 12 per cent, respectively; from 1928 to 1932 they were respectively 21 and 15 per cent, and since 1933 the five year survivals have reached 35 per cent. For carcinoma of the fundus uteri the average five year survivals have been raised from about 30 per cent prior to 1930 to 45 per cent after that year and to nearly 50 per cent after 1933. The ten year results run a close parallel to

the five year results. The results for cases in which panhysterectomy was performed as soon as the diagnosis was established and radiation therapy was administered after operation and respectively for those in which a full course of intracavitary radium and external roentgen therapy was given first and operation performed after the subsidence of the biologic irradiation effect and further irradiation was given in the postoperative period were for five year survivals 55 per cent with the first and 71 per cent with the second type of treatment. In most cases of ovarian cancer a combination of surgery and irradiation was necessary at one time or another. Whenever a patient constituted a good operative risk the large neoplastic masses were excised and irradiated. In other instances preliminary radiation therapy was given and operation was reserved until the biologic radiation reaction cleared up. In still other instances the operative procedure and the irradiation were repeated or even alternated many times for several years, depending on the clinical course. The five and ten year survivals represented broadly 20 and 18 per cent, respectively, throughout the entire period. The addition of supervoltage roentgen therapy, contrary to expectations, did not seem to influence the survival curves. This might be changed considerably with a larger series. For the 31 carcinomas of the external genitalia a combination of individualized surgery and radiation therapy was used in most cases. The five year survivals amounted to 29 per cent for the 14 cases of cancer of the labia, 10 per cent for the 10 of the vulva, and none for the 7 of the vagina. The number of cases treated with supervoltage roentgen therapy was too small to permit any estimation.

Bilateral Pneumothorax.—On the basis of data in 56 cases of bilateral pneumothorax performed at Hopemont Sanitarium, Sonneborn presents conclusions which he feels can serve as a working pattern when modified to meet the individual case: Bilateral pneumothorax is of definite value in the treatment of bilateral pulmonary tuberculosis, especially when the involvement is either moderately advanced in each lung or when it is far advanced in each lung, or far advanced in one lung and moderately advanced in the other. The series of cases presented is made up largely of the latter group. The successful results vary in inverse proportion to the extent of the disease. A period of bed rest should precede attempted collapse of those patients whose general condition is extremely poor. Collapse therapy is an adjunct to rest, and all patients should receive bed rest for twenty-four hours a day for from three to six months after the disease is apparently controlled or regressive. Whenever possible collapse procedures should be concentrated on controlling the disease in the first lung before contralateral pneumothorax is instituted, when the prognosis is much more favorable. Phrenic crush and pneumonolysis should be added whenever indicated. Frequently pneumothorax, even if not successful, may result in sufficient improvement to allow further therapy after the lung has reexpanded. Complications are twice as frequent in bilateral as in unilateral pneumothorax. Of 56 patients the disease of 19 is inactive, 2 have an active bronchitis with positive sputum but an apparently controlled parenchymal lesion, the disease of 6 has become inactive with additional procedures after reexpansion of the uncontrolled but improved lung, 13 are known to be dead and the disease of 16 is active. The disease of 4 of these 16 patients is controlled on one side with pneumothorax, and further therapy may be possible on the contralateral lung at some future date.

Acute Poliomyelitis. W. H. Kelleher.—p. 217.

*Acute Endocarditis in Infants. S. Wolff.—p. 241.

Acute Endocarditis in Infants.—Wolff cites 2 cases of acute endocarditis in infants with recovery. He believes that the number of cases of endocarditis in infants diagnosed during life and not on the postmortem table would increase considerably if physicians kept firmly in mind the triad of symptoms described by Finkelstein: pallor of face, attacks of cyanosis and accelerated respiration. An early diagnosis would probably also increase the number of cured cases. Endocarditis in infants is due chiefly to influenza or sepsis. The 2 instances reported originated from apparently harmless boils and both were due to staphylococci. The sepsis or pyemia was, in the first case, proved by the secondary focus in the parotid, in the second case by the blood culture and giant spleen, which extended to the nipple line. During recovery the spleen became continually smaller until at last it was hardly palpable. The blood culture also became negative. In contrast to the statements of Orgler and others the loud systolic murmur, as a symptom of endocarditis, could be heard from the very beginning and remained as a sign of the defect resulting from the endocarditis. The friction sound in the second case, which was due to the complicating pericarditis, disappeared after recovery. The essential point in treatment is the removal of pus from accessible places—from the boil and pericardium in the cases cited. Sulfanilamide, a specific against streptococci, had no effect, whereas blood transfusion, the highly concentrated calcium Sandoz and redoxon forte (a proprietary ascorbic acid) decidedly influenced the healing process. However, the final change was evidently due to antistaphylococcus serum. That the heart withstood the disease is certainly a result of immediate and considerable digitalization, which even caused rhythmic disturbances because of overdosage. The theoretical objections against digitalis in septic endocarditis have been disproved by Schottmüller and by Fraenkel. The greatest attention should be paid to even small boils in infants, as their early evacuation might prevent this serious disease.

Blood and Plasma Transfusion in Alimentary Hemorrhage.—Black and Smith compare the effects of citrated whole blood with those of plasma for massive bleeding from the stomach or duodenum. The 9 patients studied were bleeding severely from the stomach or duodenum; the first 3 were given massive transfusions of citrated blood by slow drip, 1 reconstituted dried serum in fourfold strength, 2 plasma infusion supplemented immediately by blood transfusion and 3 plasma alone by slow drip. One of the latter patients required whole blood five days later. In the 6 patients given plasma immediate subjective or objective clinical improvement was absent; all showed some harmful effect, and in 2 of them the reaction was so severe that massive blood transfusion had to be used at once. The chief complaints during plasma infusion were headache, faintness and a vague sense of irritability. Objectively, increase in pallor, quickening pulse and drowsiness, leading to actual unconsciousness, were observed. In 1 patient, who had a low hemoglobin at the outset, unconsciousness persisted for more than half an hour. Even after the patients recovered from the immediate effects of plasma transfusion, clinical improvement, and especially blood regeneration, were notably slower than in the patients given whole blood. The patient who was given serum, and whose plasma volume

increased only by 300 cc., was an exception to this. On the whole plasma compared unfavorably with whole blood in its effects on the blood volume and hemoglobin concentration. It did not lower the degree of azotemia to the same extent as whole blood. It is suggested that the ill effects of plasma in these cases are due to forced dilution of the blood in excess of the limits favorable to recovery from hemorrhage. Generally plasma is contraindicated when the hemoglobin is less than 50 per cent.

Trichiniasis in Hertfordshire. L. P. Garrod and D. Maclean.—p. 240.

Outbreak of Trichiniasis.—Lee cites 7 unusual cases of trichiniasis which presented atypical features. Nephritis, pneumonia, renal damage, influenza, pyrexia of unknown origin, suspected typhoid and pyelitis were the conclusions arrived at before the patients were admitted to the New Cross Hospital. The predominating signs and symptoms consisted of edema of the eyelids (the outstanding symptom in all the patients), headaches, nailbed and conjunctival hemorrhage or injection, mental torpor with lethargy, drowsiness, confusion and slowed cerebration, heaviness in the limbs, generalized aches and pains, muscular tenderness and stiffness, disturbed reflexes, paralysis and severe constipation. Two patients vomited and 1 had colic. Sheldon, a consulting physician, put forward a tentative diagnosis of trichiniasis. The fact that many of the typical symptoms of such a diagnosis were not shown by the 7 patients threw doubt on the diagnosis. However, biopsy of the pectoral muscle was performed and the diagnosis was established by the identification of *Trichinella spiralis* embryos. There was little or no capsule formation, and the opinion was that the parasite had just reached the muscle. Further confirmation was obtained when another successful biopsy was performed. The 7 patients were all admitted to the hospital within five weeks. The author suggests that the abnormal mental state appears to have been inadequately described in the past and is worthy of special note. Hemorrhages into the conjunctivas and nailbeds appear to be attributable to larval embolism. Involvement of the central nervous system was also possibly of embolic origin. The constipation was exceedingly troublesome and resulted in fecal impaction on one occasion.

Bronchitis and the Bronchial Tree. S. Engel and G. H. Newns.—p. 212.

Fluorine in Etiology of Endemic Goiter.—According to Wilson, the distribution of endemic goiter in the Punjab and in England is related to the geologic distribution of fluorine and to the distribution of human dental fluorosis (mottled enamel). Inquiry showed the presence of dental fluorosis among school children in two areas of Somerset, where two previous observers had recorded a high incidence of goiter, and the absence of dental fluorosis in an adjoining area selected as control where endemic goiter was absent. Of 378 children examined in the area mapped as endemic for goiter, 55 showed some degree of dental fluorosis, while of 103 children examined in the control area, none were affected. The author does not suggest that the presence of fluorine in drinking water is the only factor in the causation of endemic goiter in the particular regions; the intervention of other factors operating against the production of goiter may completely overcome the action of fluorine in promoting it. For instance a weekly call by a fishmonger's van at an isolated village in the coastal areas of Essex with a high degree of human dental fluorosis has been described to counteract the effects of a local deficiency of iodine.

Congenital Lack of Fibrinogen and Fibrinopenia.—According to Glanzmann and his associates, cases of hemorrhagic diathesis as the result of fibrinogen deficiency are comparatively rare in children. These cases can be classified into two groups: (1) the cases of congenital lack of fibrinogen (afibrinogenemia) and (2) the cases of fibrinopenia, which can be subdivided into hereditary fibrinopenia and acquired fibrinopenia. The authors describe in detail an instance of constitutional congenital lack of fibrinogen in a boy aged 3. They designate permanent absence of fibrinogen, incoagulability of blood, prolonged bleeding time and intermittent thrombopenia as the essential characteristics of congenital lack of fibrinogen. The outcome of the Takata-Ara reaction and the Weltmann reaction does not indicate an impairment of the hepatic parenchyma. Hemorrhagic attacks may become fatal. The development of giant hematomas, the contents of which remain fluid, is especially characteristic of congenital absence of fibrinogen. The administration of a vitamin K preparation, the intravenous injection of 10 cc. of a 20 per cent calcium gluconate, of 5 cc. of a potent ascorbic acid preparation and the local application of stryphon (a preparation of methylamino-aceto-orthodioxymethylbenzol) proved helpful in the arrest of hemorrhage. Hereditary fibrinopenia is transmitted to both sexes and usually is combined with thrombopenia; it is benign and the patients may reach an advanced age. The authors give a detailed description of a case of acquired fibrinopenia in an infant aged 8 months. The discussion of this case is followed by a comparison of congenital lack of fibrinogen and acquired fibrinopenia. The complete lack of fibrinogen is congenital, whereas fibrinopenia is acquired. In congenital absence of fibrinogen the fibrinogen is constantly lacking, the blood is noncoagulable, the bleeding time is prolonged and there is intermittent thrombopenia, whereas in acquired fibrinopenia fibrinogen is lacking only temporarily, the bleeding time is shortened, but intermittent thrombopenia exists here as in congenital lack of fibrinogen. The plasma protein picture is not greatly changed in the congenital lack of fibrinogen, but in the acquired fibrinopenia the globulin is increased. The Takata-Ara reaction is negative in the first condition but positive in the second. In congenital lack of fibrinogen there exist no signs of hepatic impairment, whereas fibrinopenia is accompanied by hepatosplenomegaly and jaundice. Whereas, in congenital lack of fibrinogen, large hematomas develop after traumas, fibrinopenia is accompanied by streaklike cutaneous hemorrhages. A vitamin K preparation seems an effective hemostatic in both conditions.

- *Acute Abdominal Syndrome from Empyema and Perforation of Lung. E. Ruggieri.—p. 1931.

Abdominal Symptoms from Empyema and Perforation of Lung.—Ruggieri reports 5 cases of acute abdominal symptoms simulating acute surgical conditions of the abdomen which resulted from acute purulent empyema in 3 cases, perforation of the collapsed lung in the course of artificial pneumothorax in 1 case and perforation of the lung into the mediastinum in another case. Purulent empyema was a complication of chronic or putrid pulmonary abscess. According to the author, when the abdominal symptoms are caused by empyema or perforation

of the lung a diagnosis can be made by an evaluation of the respiratory and abdominal symptoms. The respiratory signs on objective examination of the thorax and the roentgenograms may show the pleuropulmonary disease. In the absence of typical objective and roentgen signs, difficult and panting respiration, the given type of decubitus of the patient and the presence of cyanosis of the lips, on the one hand, and the subsidence of abdominal defense after prolonged palpation of the abdomen and absence of cutaneous hyperesthesia and of pain at the Douglas pouch during rectal examination on the other, are of diagnostic value. The abdominal symptoms due to empyema of the diaphragmatic pleura are characteristic of that location. The diagnosis of empyema following pneumothoracotomy for the treatment of purulent abscess is difficult. Egophony at the thoracotomy opening is a constant observation of diagnostic value. Dyspnea is the main symptom of spontaneous perforation of the lung whether or not complicating artificial pneumothorax. In rare cases it appears late. However, in cases of this type the nontypical symptoms of the abdomen indicate the delay of an abdominal operation, and the patient should be watched for the appearance of respiratory symptoms. When the condition develops in the course of artificial pneumothorax, the determination of the intrapleural pressure will clarify the diagnosis. In all cases the diagnosis is verified by the results of an exploratory puncture. The author believes that acute abdominal symptoms from pleuropulmonary diseases are due to acute disorders of the pulmonary circulation with consequent plethora of the splanchnic circulation.

- *Action of Staphylococcus Toxoid on Infectious Bullous Dermatitis in Children. G. Roi.—p. 197.

Action of Staphylococcus Toxoid in Bullous Dermatitis.—Roi reports satisfactory results from staphylococcus toxoid in 19 cases of infectious bullous dermatitis which occurred in a crèche. The epidemic was caused by *Staphylococcus aureus*. The patients were all infants on artificial feeding and exhibiting nutritional deficiency, avitaminosis and slight rickets. The common treatment with pomades of bacterial filtrates, anti-staphylococcus vaccines and autovaccines failed. The staphylococcus toxoid treatment was preceded by a local treatment which consisted of rupturing the bullae, painting the lesions with a 0.5 per cent alcoholic solution of methyl green and gentian violet and applying antipyrogenic pomade. The toxoid was administered in intradermal injections, beginning with a 0.1 solution of pure toxoid in sodium chloride solution and increasing to 0.3 concentration and then to pure toxoid. The injections were administered in the supraspinous region every other day up to a total of from four to eight injections. The condition rapidly improved in all cases. The staphylococcus toxoid therapy appears to be of value in the treatment of bullous dermatitis of infants and is well tolerated. The toxoid acts by diminishing the allergy caused by the staphylococcus and by establishing antitoxic immunity and diminishing the virulence of the staphylococcus.

*Puncture and Aspiration of Tuberculous Cavities. A. A. Raimondi, M. M. Brea and J. A. Taiana.—p. 330.

Puncture and Aspiration of Tuberculous Cavities.—Raimondi and his collaborators performed intracavitary aspiration by Monaldi's technic in 6 cases of pulmonary tuberculosis with stationary cavities. Aspiration was discontinued in 4 cases and continued in 2. Cavernoscopy was performed in all cases. The cavity rapidly closed in 1 case. It remains healed up to one and one-half years after the operation, as shown by roentgenograms and the absence of clinical symptoms. In 1 case the cavity reappeared after temporary closure. In 1 case spontaneous pneumothorax and fatal bronchopneumonia followed. In 1 a phlegmon of the thoracic wall and hemoptysis appeared, and the disease entered an acute course. In 2 cases the disease entered an acute course after the operation from bilateralization

in 1 and cavernization of the base of the lung in the other. The authors point out that the operation is not harmless. It may cause propagation of tuberculosis, local unfavorable reactions, operative accidents (spontaneous pneumothorax) and phlegmon of the thoracic wall, any one of which has an unfavorable action on the disease. In some cases slight movements of the aspirating catheter cause coughing. The mechanism of action of intracavitary aspiration is not clear. In cases in identical circumstances, prolonged aspiration may fail in some whereas aspiration for a short time may be followed by permanent healing of the cavity in others. In general there are but few cavities which obtain benefit from aspiration. Since the results are inconstant, it is difficult to establish proper indications of the operation.

*Primary Closure of Abdominal Cavity in Treatment of Acute Diffuse Peritonitis: Experimental Study. Y. Ishikawa.—p. 516.

Effect of Pregnancy on Malignant Tumor.—Mankin examined the controversial problem of the effect of pregnancy on existing malignant tumor on the basis of 72 cases observed in the Oncologic State Institute in Leningrad and of the extensive literature on the subject. Carcinoma of the breast (22 cases) and of the uterine cervix (22 cases) predominated. Sixty-five of the cases fell within the age level of 20 to 40 years. Pregnancy and the postpartum (or postabortion) condition evoked distinctly different reactions on tumor growth. Pregnancy did not stimulate existing malignant conditions but in many respects retarded proliferation. On the other hand, termination of pregnancy by birth or abortion significantly intensified the morbid processes and aggravated prognosis. Surgical intervention should therefore be primarily directed not to aborting the pregnancy but to the extirpation of the tumor. The etiology of these contrary reactions is to be sought in the mutual antagonism of the estrogens and luteins. During pregnancy, owing to the activity of the corpus luteum, luteins are abundant and hold the blastomogenic action of the estrogens in check. In the period after birth or abortion, with diminished activity of the corpus luteum and its derivative, the estrogens reassert their blastomogenic power. Prognosis in carcinoma of the uterine cervix was most favorable when tumor ablation and fetus removal were simultaneous or when the tumor was removed first. In fibroma of the abdominal wall, tumor extirpation is indicated as late as the sixth and seventh month of gestation. After that, surgical intervention is contraindicated because of the danger that the cicatrice left by the operation may be unable to develop sufficient resistance.

Closure of Abdominal Cavity in Peritonitis.—Ishikawa in his experimental study on 86 dogs, half of which served as controls, sought to determine the superiority of primary closure over drainage in acute diffuse peritonitis after operation. After the dogs, weighing from 10 to 14 Kg., had been paired off, a peritoneal lesion was artificially inflicted by injecting a freshly filtered fecal solution heated to normal temperature into the abdominal cavity (9 cc. per kilogram of body weight) without injuring the abdominal viscera. Laparotomy was performed in three stages, two, four and six hours after injection, and affected 13, 18 and 12 pairs of dogs, respectively. Dogs laparotomized after six hours died. The time limit of one hundred and twenty hours after injection was established as surviving time. Surviving animals were then killed. Survival rate, post-mortem observations, tests for the chloride content of the blood and for blood sugar and the erythrocyte count were all favorable to the closed method as against drainage. The mortality index for the closed method and the drainage groups were as follows: 23 per cent against 92.3 per cent laparotomized after two hours; 33½ per cent against 88.9 per cent after four hours; 66⅔ per cent against 100 per cent after six hours, an average of 40 per cent against 93 per cent. Of the third group, which

included 24 dogs, 4 dogs (none of them controls) were able to survive, though the reabsorption power of the peritoneum after six hours is greatly weakened. In no case did a control animal outlive its fellow. At necropsy, diffuse peritonitis was almost completely healed in the majority of the test dogs. In the controls, small pus formations were still found and, to a varying degree, inflammation of the mesentery, omentum, the intestinal serosa and the wall of the peritoneum persisted. The author states that the closed method has been used for years in his clinic with decidedly good results. Primary closure can be employed even in grave infections provided tamponade of purulent exudates is thorough and extensive.

Blood Changes During Suction Drainage of Cavities.—Flügge describes the behavior of the sedimentation speed of the erythrocytes and of the white blood picture in 19 cases of pulmonary tuberculosis in which suction drainage of the cavities was done. The blood picture was examined before the onset of suction drainage and at eight day intervals thereafter. The sedimentation speed was determined before the suction drainage and at four week intervals thereafter. Summarizing his observations, the author says that four phases can be differentiated in the blood of patients undergoing suction drainage. First there is the phase of the general reaction to the onset of the suction drainage; it is characterized by deviation to the left without lymphocytic crises and subsides at the latest after four weeks. The second phase is that during which sputum and drainage secretion become negative. Although the leukocyte count and the sedimentation values are increased, the noticeable lymphocytic reaction with changing number of staff-nuclear cells (depending on the severity of the secondary suppurating secretion) indicates the beginning of the curative phase. This phase persists as a rule until three months after the beginning of the suction drainage. In this phase the blood picture is a better indication of what is taking place than is the sedimentation reaction. The third phase, which is that of the cure of the cavity, extends to the withdrawal of the suction catheter. It is characterized by changing leukocyte counts and sedimentation values; the lymphocyte count is increased; the staff-nuclear count fluctuates, depending on the degree of suppurating secretion. In this phase again the sedimentation rate fails to indicate the degree of general improvement and cure. The fourth phase, which follows the treatment, is characterized by a normal leukocyte count and sedimentation value and by a persisting lymphocytic reaction without nuclear deviation.

Postoperative Reactions in Exophthalmic Goiter.—Kaspar says that in the three years from 1937 to 1939 inclusive 4,384 struma operations were performed at his hospital, of which 287 concerned cases of exophthalmic goiter. Most of these patients were subjected to preoperative and postoperative iodine

medication, but some of them proved refractory to it. In 1 patient with exophthalmic goiter, in whom the postoperative reactions were extremely severe, the author gave an intravenous injection of 40 cc. of afenil and when this effected improvement he gave another intravenous injection of 20 cc. of afenil and administered 30 cc. of calcium gluconate intramuscularly. The favorable effect of this treatment induced the author to try large doses of calcium in other patients who reacted inadequately to iodine therapy and who had severe postoperative reactions. Later he administered large doses of calcium (from 20 to 30 cc. intramuscularly) also before the operation and he found it effective in other forms of hyperthyroidism, particularly in iodine thyrotoxicoses. The intramuscular injections of calcium are made with a long needle two or three fingerbreadths below the crest of the ilium, because in this manner the annoying infiltrations are avoided. The author recommends the administration of large doses of calcium (intravenously and intramuscularly) preoperatively as well as for the frequently severe postoperative reactions, reasoning that the calcium deficiency existing in exophthalmic goiter is at least partly responsible for the postoperative disturbances and that this deficiency is favorably influenced by the large doses of calcium.

Physiologic and Pathologic Cardiac Movements. H. Jaeger.—p. 1142.

Chronic Bronchitis and Prolonged Cough in Children. W. Walther.—p. 1145.

Tuberculosis of Peritoneum.—Petermann does not consider the tuberculous peritonitis that is a partial manifestation of an acute military tuberculosis and is fatal within a short time, but only those cases in which the tuberculous process of the peritoneum dominates the symptomatology. Tuberculous peritonitis is chiefly a disease of children. The mode of infection differs; the organisms may pass through the intestinal wall or may enter by way of the vagina and the tubes, leaving these organs themselves unimpaired. Dissemination following bursting of a tuberculous mesenteric lymph node is another possible mode of infection, but most frequent is the infection by way of the lymph channels. Hereditary predisposition is an endogenous etiologic factor. Exogenous etiologic factors are undernourishment and poor hygienic conditions. The early stage of the disease has only indefinite symptoms. The general condition is impaired, the appearance is poor and there are complaints of dyspeptic disturbances, of recurrent abdominal pains and frequently of diarrhea. Tuberculous peritonitis should be thought of, if these symptoms cannot be explained by helminthiasis or by disease of an abdominal organ. The second stage is characterized by the complete symptomatology and requires energetic treatment. During the third stage, complications develop which are decisive for the prognosis. Increase in the size of the abdomen is characteristic. The intestinal function is impaired. The author differentiates three forms of tuberculous peritonitis: the serous form with profuse exudation, the dry form with adhesions, indurations and nodular tumors, and finally the purulo-ulcerous or the caseous form, which leads to the formation of abscesses or perforations into the intestine. It is not always possible to differentiate these three forms strictly. Fresh air, sunshine and a rich diet are helpful in tuberculous peritonitis as in other forms of tuberculosis. Climatic therapy, particularly in the form of the high mountain climate, is also helpful. Surgical therapy, that is, laparotomy with evacuation of the exudate, has been employed with considerable success particularly in the exudative form. Extremely advanced tuberculous peritonitis and involvement of other organs are contraindications to laparotomy. The operation must be followed by energetic general treatment. Recurrent exudates can be counteracted by puncture, but early exudates should not be punctured because of their bactericidal effect. Insufflation of air or oxygen has been recommended following removal of the exudate. The author thinks that the efficacy of this measure is due to the hyperemia it induces and to the stimulation of the leukocytosis. He emphasizes that the

insufflation must be done with great caution. Tuberculin treatment can be employed as a supporting measure and demands strict individualization.

Acute Otitis Media. R. Perwitzschky.—p. 1167.

*Whole Grain Bread, the Bread of the Future. W. Heupke.—p. 1172.

Whole Grain Bread.—Heupke stresses that in the average diet now available in Germany the supply of vitamin B₁ will be adequate only if a considerable portion of the bread consumed is of the whole grain type. Whereas 400 Gm. of rye whole grain bread contains 840 micrograms of vitamin B₁, the more refined types of bread contain only from a sixth to a fourth of this amount. Moreover, it is known that the vitamin B₁ requirements are the greater the higher is the sugar and starch content of the diet. In view of the high carbohydrate content of the present day diet, the use of whole grain bread is a necessity in order to insure an adequate supply of vitamin B₁. Vitamin B₁ is found exclusively in the grain germ and in the aleuron layer, that is, in those parts of the grain which are removed in milling the flour for the refined types of bread, whereas they remain in the flour used for the whole grain type of bread. The grain germ contains other valuable substances such as lactoflavin, vitamin A and vitamin E. Whole grain bread differs from refined bread also in protein, starch and mineral contents. The germ of the grain and the aleuron layer contain more valuable proteins than do the other parts of the grain, and for this reason the whole grain bread contains more valuable proteins than do the refined breads. Furthermore, the refined breads contain few minerals, because phosphoric acid, calcium, magnesium and iron are found chiefly in the external layers of the grain. Other valuable constituents of whole grain bread but not of refined bread are the auxins or growth substances. The greater nutritional value of whole grain bread has been proved by feeding experiments on animals. It has been proved that whole grain breads are valuable for the development and preservation of teeth and in the prevention of chronic constipation. The use of whole grain breads is now advocated in all civilized countries.

*Two Cases of Pituitary Dwarfism. F. Hayasi.—p. 2899.

*Studies in the Excretion of Bismuth. T. Seki.—p. 2925.

Pituitary Dwarfism.—Hayasi reports two cases of pituitary dwarfism (Erdheim) or nanosomia infantilis (Hanseman) in male subjects, both 19 years old, and one having physical measurements corresponding in normal subjects to those of 9 years and the other to those of 11 years. The physical development of both patients was normal in every respect until just prior to the advent of pubescence (about 8 years in the first case, and about 10 years in the second), when definite retardation began to set in suddenly but without disturbance in the general ratio of physical measurements. In both cases the roentgenographic evidence of diagnosis consisted in the general arrest in the development of the hypophysis cerebri, since the configuration of the sella turcica was normal but decidedly small as compared with that of a normal subject of the same age and sex. The first patient showed signs of Fröhlich's syndrome with adiposity around the girdle and genital infantilism; the second subject exhibited evidence of myxedema. Neither patient had diabetes insipidus, hemianopia or increased intracranial pressure; no hyperplasia of the thyroid glands was present. There was a retardation in the epiphyseal union at the ends of the long bones. The first patient gave evidence of a slight tendency to hypersensitization to pilocarpine while the second was sensitive to atropine. To one of these patients, showing myxedema, the author administered thyroid for three months, and there was some improvement in the condition of his skin, but no other noticeable changes occurred.

Excretion of Bismuth.—Seki presents results obtained by quantitative determinations of bismuth excreted in saliva and in urine in three patients who had received courses of antisyphilitic treatment with salts of this metal. At the time of these observations the patients had received bismuth in total amounts varying from 0.95 to 2.16 Gm. over periods of months,

so that for the purpose of the tests the storage of bismuth was considered adequate. The purpose of the study was to ascertain the effect of pilocarpine and epinephrine injections on the excretion of bismuth in such patients. Urinary bismuth was first determined and found to be excreted to the amount of 0.08, 0.23 and 0.71 mg. in single specimens passed in one hour. Considering the quantity excreted by the first patient as 1, the ratio of urinary bismuth excretion in these three patients was 1:2.7:8.6. The serum bismuth per cubic centimeter gave the values of 0.0024, 0.0037 and 0.0053 mg. respectively, or a ratio of 1:1.6:2.2. The bismuth content of saliva per cubic centimeter was likewise determined and was found to be 0.00053, 0.00066 and 0.00070 mg. respectively, or a ratio of 1:1.2:1.3. Following the injection of 0.5 cc. of 2 per cent solution of pilocarpine hydrochloride in these patients, the excretion of bismuth increased in proportion to the body store concomitant with the increase in salivary flow up to the end of two hours. After two hours the quantity of bismuth excretion in the saliva decreased. The quantity of urine decreased after the pilocarpine injection. On the other hand, the injection of 0.6 cc. of epinephrine hydrochloride caused only a slight change, if any at all, in the urinary excretion of bismuth by these patients.

*Arsphenamine Therapy of Septic Scarlet Fever. B. P. Brukhanskiy, N. A. Tsukerman and E. I. Kaminskiy.—p. 15.

Arsphenamine Therapy of Septic Scarlet Fever.—Brukhanskiy and his associates report 28 cases of septic scarlet fever in which arsphenamine therapy was used. Four of the patients died and 24 recovered. The ages of the patients varied from 1 to 15 years. The earliest effect was seen in the diminution or disappearance of the necrotizing process in the pharynx and striking improvement in the general condition. The fetid, ichorous discharge from the nose disappeared, as a rule, on the day after administration of the drug. Enlargement of the cervical lymph nodes and edema of the cellular tissue of the neck rapidly regressed. Cardiac function rapidly improved, and symptoms of adrenal insufficiency receded. The following complications were noted among the 28 patients who recovered: 2 had nephritis and 5 otitis media. The authors feel that better results could be accomplished by early exhibition of the drug. Most of their patients received the drug on the third to seventh day of the sickness. Untoward effects of arsphenamine injections can be avoided by strict individualization of the dose, which should not exceed 0.009 Gm. to 1 Kg. of weight in any instance.
